

*The Mission: Human Capital Transmission, Economic Persistence and Culture in South America**

Felipe Valencia Caicedo[†]

November 25, 2014

Abstract

This article examines the long-term consequences of a historical human capital intervention. The Jesuit order founded religious missions amongst the Guarani, in modern-day Argentina, Brazil, and Paraguay. Missionaries instructed indigenous inhabitants in reading, writing and various crafts, before their expulsion in 1767. Using archival records and municipal census data, I demonstrate that educational attainment was and remains higher after 250 years in areas of former Jesuit presence. These differences also translate into 10% higher incomes. The effect of Jesuit missions emerges clearly after comparing them with abandoned Jesuit missions, Franciscan Guarani Missions and using an Instrumental Variables strategy. In addition, I collect survey data and conduct behavioral experiments, finding that respondents in missionary areas exhibit higher non-cognitive abilities and collaborative behavior. Such enduring differences are consistent with transmission mechanisms of occupational persistence, inter-generational knowledge transmission and indigenous assimilation. Robustness checks suggest that the results are not driven by migration, urbanization and tourism.

“When in 1768 the missions of Paraguay left the hands of the Jesuits, they had arrived at perhaps the *highest degree of civilization* to which it is possible to conduct a young people.” “The Jesuits have civilized the [natives], have taught them to be *industrious*, and have succeeded in governing a vast country (...) [making] a virtue of subduing savages by mildness and *instruction*.”

Voltaire, 1756 and 1770.¹

1 Introduction and Motivation

The importance of history for economic development is now well established; historical shocks and “critical junctures” have been shown to influence modern outcomes through geography and natural endowments, legal origins and institutions, genetics, human capital and culture.² Although historical persistence of outcomes appears to be strong in many cases, the channels of transmission are less clear. Focusing on extractive institutions, Dell (2010) stresses the negative effect of the *mita* labor system in Latin America and Nunn and Wantchekon (2011) document the adverse effect of African slavery through decreased trust. Less is known, however, about how other colonial arrangements might have led to *positive* outcomes in the long run. While Europeans often imposed extractive institutions and created exploitative economic relationships (Acemoglu et al. 2001), they also transferred human capital, cultural values and technological know-how (Glaeser et al., 2004), which may have led to beneficial effects in the long run.

In this paper, I demonstrate the important benefits of European missionary activity in South America. Jesuit missionaries travelled to what were essentially the backwaters of the Spanish and Portuguese empires, before being expelled from the continent in 1767. While religious conversion was the official aim of the missions, they also increased human capital formation as a result of schooling children and training adults in various crafts.³ I focus on the repercussions of the Guarani

¹*Histoire Philosophique et Politique des Indes* (1770) and *Essay on the Customs and the Spirit of the Nations* (1756). In Graham (1901), p. 52. Emphasis added.

²The literature on historical persistence has been recently summarized in Nunn (2009 and 2013), and Spolaore and Wacziarg (2013). Seminal papers on these determinants include Diamond (1997), Engerman and Sokoloff (1997), Gallup et al. (1999), La Porta et al. (1998), Acemoglu et al. (2001 and 2002), Ashraf and Galor (2013), Glaeser et al. (2004) and Landes (1998).

³Compared to McCleary and Barro (2003 and 2006), I focus less on the direct effects of religion and more on its human capital externalities (Glaeser and Sacerdote, 2008; Becker and Woessmann, 2008 and 2009).

Jesuit Missions in modern-day Argentina, Brazil and Paraguay. In municipalities where the Jesuits carried out their apostolic efforts, median years of schooling and literacy levels remain markedly higher after almost 250 years. These differences in educational attainment have also translated into higher modern per capita incomes of nearly 10%. To explain such enduring differences, I analyze cultural outcomes and persistence mechanisms. I conduct a household survey and perform experiments with indigenous inhabitants in Paraguay to better understand the mechanisms at play. I find that respondents in missionary areas have higher non-cognitive abilities and exhibit more pro-social behavior. I also find that people closer to missionary areas specialize in relatively more skilled labor, moving away from agriculture and towards manufacturing and services.⁴

The literature on persistence and the after-effects of colonialism raises several important questions. First, identification is often challenging because the factors that led to differential treatment are often geographic in nature and can be argued to have independent effects on modern-day outcomes.⁵ Other studies simply assume that variation in long-ago samples is plausibly random (Guiso et al. 2008; Voigtländer and Voth 2012). Second, historical shocks are often confounded with national institutional trajectories that have been shown to have a long-lasting effect. Meanwhile, a large literature has stressed the importance of human capital for modern economic growth at the macro level and personal income at the micro level.⁶ Yet questions remain about the persistence and transmission mechanisms of human capital shocks, especially during historical times (Waldinger, 2012). Can a one-off human capital intervention have long-lasting effects?

The Jesuit conversion (and education) of the Guarani allows for clean identification of the causal effects of religious missionaries. I exploit the fact that Jesuits were expelled from the Americas in 1767, following political disputes in Europe. This event precludes any direct continuation effect as a result of enduring treatment. The political rupture between the Jesuit order and the Spanish Crown was arguably exogenous to the location of proselytizing activities amongst the Guarani.

⁴As has been argued with respect to the Jewish population by Botticini and Eckstein (2005, 2007 and 2012).

⁵The direct effect of geographic factors has been stressed by, among others, Gallup et al. (1999), Rappaport and Sachs (2003), and more recently by Nunn and Puga (2012).

⁶Mankiw et al. (1992), Benhabib and Spiegel (1994), Barro (2001), Glaeser et al. (2004), Heckman (2000), and Hanushek and Woessmann (2008).

Therefore, before-and-after identification provides an ideal setting for examining the persistence of income, human capital and culture.⁷ The early stage of development of the indigenous inhabitants makes the setting unique. To disentangle the national institutional effects from the human capital shock, I focus on fine-grained within country variation in missionary activity in three different countries.⁸ The area under study was populated by a single semi-nomadic indigenous tribe, so I can abstract from the direct effects of pre-colonial ethnic tribes (Maloney and Valencia Caicedo, 2012; Michalopoulos and Papaioannou, 2013). The Guarani area has broadly similar geographic and weather characteristics, nonetheless, I control for a host of variables in the estimation. Crucially, I compare outcomes in areas where the Jesuits were active before 1767 with those where they *attempted* to establish missions early on. I also conduct a direct comparison with neighboring Franciscan Guarani Missions, which did not stress education in their conversion.

The virtues and vices of the Jesuit Catholic missions were hotly debated by prominent contemporaries and have been a major topic of study for historians ever since. The Guarani Missions constituted a large social experiment, and at their peak in 1730 involved more than 120,000 indigenous people (see Figure A.1). According to Voltaire (1756), who was a fierce critic of the Church, missions had a positive effect in terms of industriousness and education.⁹ Missions were seen as a New World Utopia that stood in stark contrast to European corruption and decay.¹⁰ Even though volumes have been written about the history of the Jesuit Missions of South America, little is known about the long-term economic consequences of these religious institutions. This study aims to address this gap in the literature.

To assess the impact of the Guarani Jesuit Missions I assemble a novel data set that combines archival information about the missions with modern outcomes at the municipal level. The geo-

⁷The effect of Protestant missions has also been analyzed by Nunn (2010 and forthcoming) for the African case.

⁸To do so, I employ country and state-fixed effects.

⁹Indeed, Voltaire sent *Candide* to visit and aid the Jesuits of Paraguay, a praise also shared by Montaigne and Montesquieu.

¹⁰Other contemporaries and historians such as Palafox (1600-1659) and Popescu (1967) –and even the current Pope– have been more critical of the so-called “Jesuit Republic of Paraguay”. Pope Francis, the first Jesuit Pope of the Catholic Church, declared on his official visit to Paraguay: “The truth is that what [the Jesuits] left, with the reductions [missions], are many ruins.” Quoted in *La Nación* newspaper, Argentina on November 25, 2013 [author’s translation].

coded data set covers the municipalities in the states of Misiones and Corrientes in Argentina, Rio Grande do Sul in Brazil, and Misiones and Itapua in Paraguay (Figures 1 and 2). With this setup I can also study the outcomes of interest in places with different national histories and institutions. In addition to using modern-day and archival data, I collect household survey data from a stratified sample in Southern Paraguay. Combining cultural questions with experiments from the psychology literature, I investigate non-cognitive skills and attitudes in areas with and without a former Jesuit missionary presence (Figure 3). It is worth noting that Paraguay as a whole has received little attention in economics.¹¹

In order to quantify the Jesuit missionary treatment I use as main variable distance to the nearest mission.¹² I then estimate an econometric model of modern outcomes –such as education and income– based on this measure of missionary presence. I find a positive effect on educational attainment of 15% (.8 median years of schooling) and income of 10%. The human capital effects are greater during historical periods and both effects appear larger at the local level. Nonetheless, the location of the Jesuit Missions can be still be endogenous. Even though I use fixed effects and control for a large set of relevant geographic and weather characteristics, Jesuit missionaries might have chosen favorable locations beyond such observable factors. Hence the positive effects observed might be due to this initial choice and not to the missionary treatment *per se*.¹³

To address the potential endogeneity of missionary placement, I conduct two empirical tests. The first one is a placebo test that looks at missions that were initially founded by the Jesuits but were abandoned early on (before 1659). I can thereby compare places that were initially picked by the Jesuit missionaries with those that actually received the missionary treatment.¹⁴ I find no effect for the missions that were abandoned by the Jesuits early on, which suggests that what mattered in the long run it is what they did and not where they first settled. Second, I conduct a comparison with the neighboring Guarani Franciscan Missions. The comparison is relevant in

¹¹Two notable exceptions being Schechter (2007) and Finan and Schechter (2012).

¹²Alternatively, I use a dummy variable for whether or not the municipality had a mission.

¹³I quantify this possibility by calculating Altonji ratios (Altonji et al. 2005), which suggest that selection on unobservables would have to be more than 4 times larger than selection on observables to drive the results.

¹⁴In the spirit of Michaels (2008) and Greenstone et al. (2010).

that both orders wanted to convert souls to Christianity, but the Jesuits emphasized education and technical training in their conversion. Contrary to the Jesuit case, I find no positive long-term effect –on either income or education– for Franciscan Guarani Missions.

I also employ an instrumental variables (IV) strategy, where I use as instruments the distance from early exploration routes and distance to Asuncion. The distance from the exploration routes of Mendoza (1535-1537) and Cabeza de Vaca (1541-1542) serves as a proxy for the isolation of the Jesuit missions (in the spirit of Duranton et al. 2014). Asuncion, in turn, served as a base of missionary exploration during the foundational period, but became less relevant for Rio Grande do Sul after the 1750 Treaty of Madrid transferred this territory to Portuguese hands.¹⁵ For this reason and to avoid the direct capital (and Spanish Empire) effects, I use this variable only for the Brazilian subsample of my data. The first-stage results are strongly significant throughout (with F-statistics well above 10), and the coefficients for literacy and income retain their sign and significance –appearing slightly larger– in the IV specifications.

To complete the empirical analysis, I examine cultural outcomes and specific transmission mechanisms that can sustain human capital transmission from the missionary period to today. I find that respondents in missionary areas possess superior non-cognitive abilities, as proxied by higher “Locus of Control” scores.¹⁶ Using well-known experiments from the behavioral literature, I also find that respondents in missionary areas exhibit greater altruism, more positive reciprocity, less risk seeking and more honest behavior. I use priming techniques to further investigate whether these effects are the result of greater religiosity –which appears *not* to be the case.

More generally, I find that municipalities closer to historic missions have changed the sectoral composition of employment, moving away from agriculture and towards manufacturing and services.¹⁷

¹⁵This identification strategy is similar to the one employed recently by Becker and Woessmann (2009) using distance to Wittenberg and Dittmar (2011) with distance to Mainz.

¹⁶This psychological test categorizes a respondent’s attitude on a scale that ranges from purely external or low locus of control (“destiny is predetermined”) to the exact opposite (“I alone control my own destiny”). For the economic relevance of these measures, see Heckman and Rubenstein (2001) and Heckman et al. (2006).

¹⁷Again, this result is consistent with Botticini and Eckstein’s (2005, 2007 and 2012) findings for the Jewish population.

In particular, I document that these places still produce more handicrafts such as embroidery, a skill introduced by the Jesuits. People closer to former Jesuit missions also seem to participate more in the labor force and work more hours, consistent with Weber (1978 and 2011). I also find that knowledge –of traditional medicine and myths– was transmitted more from generation to generation in the missionary areas. Unsurprisingly, given their acquired skills, I find that indigenous inhabitants from missionary areas became differentially more assimilated into colonial and modern societies. Additional robustness tests suggest that the missionary results are not driven by migration, urbanization or tourism.

The rest of this paper is organized as follows. Section 2 provides the context in terms of the relevant literature, historical background and geographical setting. Section 3 describes the data and presents the empirical strategy. Section 4 contains the main results on education, income and culture. Section 5 provides empirical extensions and alternative estimations. Section 6 discusses transmission mechanisms and robustness checks. Section 7 concludes.¹⁸

2 Context

2.1 Related Literature

This article builds on the literature dealing with historical development, which has been recently summarized by Nunn (2009 and 2013), and Spolaore and Wacziarg (2013). The literature has moved away from cross-country studies and towards analyses within countries or using data at the sub-national level (Banerjee and Iyer 2005; Nunn 2008; Bleakley and Lin 2012; Bruhn and Gallego 2012; Naritomi et al. 2012; Dell 2012; Gennaioli et al. 2013; Jha 2013; Michalopoulos and Papaioannou 2013). This piece relates more specifically to the literature on the long-term impact of colonialism and colonial investments (Feyrer and Sacerdote, 2009; Huillery, 2009; Dell 2010; Bruhn and Gallego 2012; Becker et al. 2014). I contribute to this literature with an exploration of the empirical mechanisms behind economic persistence, and the positive long-term effect of a

¹⁸The Appendix contains a data section and additional results.

specific colonial institution: religious missions.

Of particular relevance to the current work are studies that emphasize the role of human capital for long-term economic development. Seminal pieces by Benhabib and Spiegel (1994), Mankiw et al. (1992), Barro (2001) and Glaeser et al. (2004) stress the importance of human capital accumulation for growth. Micro evidence from Heckman (2000), and Hanushek and Woessmann (2008) points in the same direction for personal income. Questions remain, however, about the degree of persistence and channels of transmission of human capital shocks (Waldinger, 2012).

Cultural explanations of economic performance date back to Max Weber's Protestant work ethic hypothesis (Weber, 2011). The importance of cultural norms for economic activity has been restressed by Greif (1993 and 1994) and Putnam et al. (1994). Both the positive (Guiso et al. 2008, Tabellini 2008) and negative (Grosjean, 2010; Voigtländer and Voth) long-term effects of culture have been documented in the literature. Such historical studies avoid the issue of reverse causality, but cannot disentangle the continuation effect of the phenomena analyzed, be it social capital or anti-Semitism. To avoid this problem I exploit the fact that Jesuits were expelled from the Americas in 1767, due to exogenous reasons. An outstanding empirical question is whether cultural traits are transmitted horizontally or vertically, as in the theoretical models of culture of Cavalli-Sforza and Feldman (1981), Boyd and Richerson (1985), and Bisin and Verdier (2000 and 2001).

Religion is a fundamental aspect of culture. Classic papers on this topic include Iannaccone (1990), and McCleary and Barro (2003 and 2006), and modern re-interpretations include Becker and Woessmann (2008 and 2009), Botticini and Eckstein (2005, 2007 and 2012), and Cantoni (forthcoming). An emerging literature has explored the long-term effects of nineteenth-century Christian missions in Africa. At the country level, Woodberry (2004 and 2012), and Lankina and Getachew (2012) find a positive effect of Protestant missions on democracy.¹⁹ At the sub-national level, Nunn (2010) finds that missions resulted in higher levels of religiosity, Gallego

¹⁹For a more critical view, see Frankema (2012).

and Woodberry (2010) and Nunn (forthcoming) find a positive effect on educational attainment, and Cagé and Rueda (2013) on political participation. Acemoglu et al. (2014) use Protestant missions as instruments for education to argue that institutions had a significant impact on long-run development. Within countries, Wantchekon et al. (2013) find positive human capital externalities from religious schools in Benin, and Okoye and Pongou (2014) on school provision in Nigeria.²⁰ Outside Africa, Mantovanelli (2013) reports a positive effect of Protestant missions on Indian literacy and Ying Bai and Kung (2011), and Chen et al. (2013) on Chinese economic performance.

I contribute to the emerging missionary literature in several ways. By focusing on Africa and excluding Latin America from the analysis the existing papers have essentially neglected an area with one of the most intense missionary presences.²¹ I also go further back in time –from the nineteenth to the seventeenth century– and focus on Catholic as opposed to Christian missions.²² Perhaps more importantly, I address directly the endogeneity of missionary location with a placebo tests and an instrumental variables strategy. I also exploit the 1767 expulsion of the Jesuits, which precludes a direct continuation effect. Finally, I identify novel cultural mechanisms through which missions may have had a persistent effect on income and education.

This paper also contributes to the literature on the historical determinants of schooling. Gallego (2010) argues for the importance of democracy and political decentralization. Rocha et al. (2013), look at the role of European settlement communities in the state of São Paulo, Brazil. Complementary evidence is presented by Summerhill (2010), and de Carvalho Filho and Colistete (2010 and 2011), who also examine the role of slavery and historical inequality in Brazil. Musacchio et al. (2014) look instead at the interaction between political decentralization and commodity booms during the nineteenth century. Though I also focus on the historical determinants of schooling at the sub-national level, I go further back in time, stressing a different determinant and specifying potential channels of transmission in Argentina, Paraguay and the Brazilian state of Rio Grande

²⁰For similar within-country evidence, see Wietzke (2014) for education in Madagascar and Meier zu Selhausen (2014) for female empowerment in Uganda.

²¹For a notable exception in the case of Mexico, see Waldinger (2013).

²²See, for instance, McCleary and Pesina (2011) for the case of Guatemalan Christian missions during the early twentieth century.

do Sul.

Lastly, this paper relates to the literature on technological transfer in a historical setting. Spolaore and Wacziarg (2009), Comin et al. (2010) and Maloney and Valencia Caicedo (2014) demonstrate the very long-term effects of technological shocks. Dittmar (2011) argues that the introduction of the printing press had a positive impact on urban growth in Europe between 1500 and 1600; Hornung (2014) finds a positive effect for the Huguenot diaspora in Prussia; and Squicciarini and Voigtländer (2014) relate industrialization to *Encyclopédie* subscriptions in France. In this paper, I document the differential usage of technologies (e.g., embroidery and accounting) introduced by Jesuit missionaries.

The historiography of the Guarani Jesuit missions is vast and I present only a brief summary here. Primary sources include the *Cartas Anuas* (annual letters) written by such Jesuits Fathers as Ruíz de Montoya, Cardiel and Charlevoix on the state of affairs of the missions. Hernández (1913), Furlong (1955), and more recently Palacios and Zoffoli (1991) and Carbonell de Massy (1992), provide detailed accounts of the history of the Guarani Jesuit Missions. Ganson (2003) and Wilde (2009) offer a revisionist interpretation constructed around Guarani ethno-history. Demographers Maeder (1995), Livi-Bacci and Maeder (2004), and Jackson (2008) find that, despite wars and epidemics, Jesuit Missions had a positive impact on the Guarani population. Alden (1996) gives a comprehensive history of the Society of Jesus in Portugal and the Portuguese Empire, and Sarreal (2014) focuses on the history of Jesuit territories during the eighteenth century. Even so, there is a lack of empirical studies in economics that scrutinize the Guarani Jesuit missions in South America.

2.2 Historical Background

The history of the Jesuits spans volumes, so I provide just a sketch here. The Society of Jesus was founded during the European Counter-Reformation in 1534 at the University of Paris by the Basque knight St. Ignatius of Loyola *ad maiorem Dei gloriam* [for the greater glory of God]. From

the outset it stressed human capital and Papal obedience (Figure 4). It is a relatively new Catholic order when compared to the Order of Saint Benedict (founded in 529), as well as the Franciscan, Dominican and Carmelite Orders (all founded in the 1200s). The Jesuits were then the last major Catholic order to arrive in the Americas through the Spanish and Portuguese empires. Religion was –along with profit making and a desire for adventure– one of the main reasons for embarking to the New World.

The first Jesuits arrived in South America at Salvador de Bahia, modern-day Brazil, in 1549 (Bethell 1984, chapter 14). The Jesuits followed a two-pronged strategy: educating the elites in the major colonial capitals (Mexico City, Lima, Bogota and Quito) while developing indigenous missions in some of the most isolated areas of the Spanish and Portuguese empires (Bethell 1984, chapter 15). The first Jesuit mission in South America was established in Juli in 1565 in modern-day Puno, at the border of Bolivia and Peru. The Jesuits also started missions in Mainas (Peru), Moxos and Chiquitos (Bolivia), Casanare and Orinoco (Colombia and Venezuela), Baja California (Mexico), and California (United States).²³ Outside the Americas, the Jesuits established missions in China, India and Japan in the sixteenth and seventeenth centuries.²⁴

Without a doubt, the Guarani missions in modern-day Argentina, Brazil and Paraguay constitute the heart of the Jesuit missionary efforts. The Jesuits arrived in Asuncion, Paraguay, on August 11, 1588.²⁵ From Asuncion, they explored the surrounding area and established the first Guarani Jesuit Mission in 1609. The Jesuits were not the first to establish religious missions in the Guarani area; the Franciscans established their first Guarani mission in 1580 (Duran Estragó, 1987).²⁶ The Jesuit foundation was followed by a period of exploration that lasted for fifty years, until 1659 (Figure 4).²⁷ The Jesuits founded a total of 30 missions or *reducciones* (reductions) in the modern-day territories of Argentina, Brazil and Paraguay (Figure 1 and Table A.1). At their peak, the Guarani Jesuit Missions involved more than 100,000 inhabitants (Figure A.1), four times the

²³For an account of the California missions, see Bolton (1917).

²⁴Though I focus on the Guarani area, in principle the geographical dispersion of the Jesuit missions makes it possible to test the external validity of my results.

²⁵Distance to Asuncion will be analyzed in the Instrumental Variables Section.

²⁶The role of the Franciscan Missions will be analyzed empirically.

²⁷Missions that were founded but abandoned early by the Jesuits will be studied in the Placebo Section.

population of Buenos Aires in 1779.²⁸ Guarani Jesuit Missions constituted one of “the most original experiments of the spiritual conquest of the New World” (Roa Bastos, in Saguier, 1991, p. 9).

The Jesuit order’s focus on human capital cannot be overemphasized. Furlong and Storni (1994) stress the Jesuit contributions to advanced human capital in terms of cartography, ethnography, linguistics, botany, mathematics and medicine, among others. Jesuits were at the technological frontier of the time, and their cultural contributions to both music and the arts are well renowned. They introduced the printing press to Argentina, Brazil and Paraguay, and they even established an astronomical observatory in San Cosme and Damián (Paraguay).²⁹ It is worth noting that the printing press was not formally introduced into Brazil until the Portuguese court arrival in 1807 (Landes, 1998, p. 134). Jose de San Martín, who would go on to lead the independence movement of the Southern Cone, was born at the Jesuit mission of Yapeyú, in Corrientes, Argentina.

Even though the official aim of the missions was to convert souls to Christianity, the Jesuits taught children (boys *and* girls) how to read and write and carry out basic arithmetic. They also trained adults in masonry, wood carving and embroidery (Gálvez, 1995). This emphasis on education can be seen in Figure A.2, which reproduces a historical blueprint of the emblematic Guarani mission of San Ignacio de Miní, Argentina. Right next to the main square and the church, can be seen the school (*colegio*) for children along with the workshop (*taller*) for adults. For the Guaranis, the missions provided not only educational opportunities but also security and protection. The communities were self-sustaining and thrived raising cattle and producing *yerba mate* (Paraguayan tea).

The expulsion of the Jesuits represents a major event in the history of colonial Latin America. After intense political fights in Europe, the Jesuits were expelled from Spain and Portugal –and from their Latin American colonies– in 1767. Kings Charles III of Spain and Joseph I of Portugal, counselled by the Marquis of Pombal, pressured the (Franciscan) Pope Clement XIV to issue an

²⁸Ganson (2003) reports a maximum of 141,182 people in 1732.

²⁹Books were printed in the missions of Santa María la Mayor and San Francisco Xavier (Ganson, 2003).

order of expulsion.³⁰ The order was carried out with surprising efficacy in the Guarani area by Francisco de Paula Bucarelli, the Governor of Buenos Aires. Clement XIV proceeded to dissolve the Jesuit order in 1773. The Jesuits were exiled to Ferdinand the Great's Prussia and Catherine the Great's Russia and the order was not restored until in 1814 by Pope Pius VII. Due to European political fights, the Jesuits were never to return to the Guarani area.

2.3 Geographic Context

The Latin American Jesuit Missions were located in what were essentially frontier lands of the Spanish and Portuguese empires (Bolton, 1917). The case of the Jesuit Guarani lands was no different, located in the border of modern-day Argentina and Brazil, and neighboring the buffer state of Uruguay (Figures 1 and 2). Although quite specific, the area under consideration is not small and is comparable in size to Uruguay or Ecuador.³¹ The Spanish Crown viewed these missions as a tool for incorporating people into the empire (Sarreal, 2014). Even though Paraguay was an important territory for the Spanish Empire at the time, the Jesuit Missions were isolated from the colonial capital of Asuncion, which itself numbered 6,451 inhabitants in 1761 (Ganson, 2003).³² Jesuit missions were also located far away from the state capitals of Corrientes (founded in 1588), Villarica (founded in 1682) and Porto Alegre (founded in 1772). Jesuits missionaries went to an area that remains inaccessible even by modern standars.³³

The Guarani area was populated by the same indigenous tribe, also known as the *Tupis* in Portuguese. The Guaranis were semi-sedentary, and cultivated manioc root and maize through slash-and-burn agriculture. When the Jesuits arrived, the Guarani were considered to be at a Neolithic stage of development, lacking iron weapons and tools (Ganson, 2003). Hence the colonial human capital intervention took place in a primeval setting. By focusing on the Guarani area I abstract from the direct effects that different pre-colonial ethnic tribes have been shown to have in Africa

³⁰The order became effective in 1759 in Portugal and the Portuguese territories and in 1767 in Spain and their Spanish counterparts.

³¹Also similar in size to Italy or the US state of Arizona.

³²Buenos Aires and São Paulo lay even farther away from the missions.

³³The remoteness of the missions will be exploited in the IV strategy.

and the Americas (Gennaioli and Rainer 2007; Michalopoulos and Papaioannou, 2013; Maloney and Valencia Caicedo, 2012). The zone is covered by subtropical forests, its climate is humid, and the area contains no major mineral resources (Palacios and Zoffoli, 1991).

3 Data and Empirical Strategy

3.1 Data

I use archival records, government census data and household surveys to run my empirical analyses. To extract usable data from historical sources, I use ArcGIS. An example can be seen in Figure A.3., which shows a historical map of the Jesuit Missions of Paraguay. My data set covers (all municipalities of) five states in three countries (Figure 2); namely, the states of Misiones and Corrientes in Argentina, Rio Grande do Sul in Brazil, and Misiones and Itapua in Paraguay. In total, there are 578 observations, covering around ten million inhabitants, that correspond to the municipal or third level divisions for these countries (*departamentos* in Argentina, *municipios* in Brazil, and *distritos* in Paraguay).

The data for this paper come from three separate sources. First, there is information taken from historical archives on the location, year of foundation, population and general workings of the Guarani Jesuit Missions.³⁴ Additional historical data come from the National Censuses of Argentina in 1895 and 1914; Brazil in 1890, 1920 and 1940; and Paraguay in 1950.³⁵ Second, there is an extensive set of geographic and weather controls at a highly disaggregated level from BIOCLIM³⁶. Third, there are a series of educational outcomes (median years of schooling and literacy) and income (or poverty) measures from modern censuses for Argentina (2001, 2010), Brazil (2000, 2010) and Paraguay (2002, 2012). Modern data are in turn complemented by a household survey I conducted in Southern Paraguay (Figure 3), as well as by two specialized survey modules on culture from the 2006 Brazilian Municipal Survey and the Paraguay Public

³⁴These include the *Archivo de Indias* (Seville), *Archivo General de la Nación* (Buenos Aires), *Archivo Nacional* (Asuncion) and the Roman Jesuit Archives (Vatican).

³⁵This is the first national official Census of Paraguay.

³⁶<http://www.worldclim.org/bioclim>

Household Survey of 2012.³⁷ The specific variables used along with their sources and units are described in detail in the Data Appendix.

Summary statistics for some of the key variables can be found in Table 1, divided into income, education, Jesuit missionary presence, geographic and weather characteristics.³⁸ Aside from standard measures, I include more sophisticated controls, such as ruggedness and distance to rivers that may have been relevant for missionary settlement. Log income is 5.67 R\$, median years of schooling 5.08 and literacy levels border 90%, which are typical values for Latin American developing countries. Summary statistics for the household survey are presented in Table 2, divided into missionary and non-missionary areas.³⁹ There are no significant differences between the two in terms of demographic characteristics, and some differences in geographic features that I take into account in the estimation. Respondents in missionary areas appear more altruistic and honest, and exhibit a higher (internal) locus of control, differences that I analyze further in the Experimental Evidence section. These data are complemented with a series of outcomes from historical censuses, cultural variables as well as additional demographic, economic and labor characteristics. These data allow for the estimation of heterogeneous effects, the exploration of specific mechanisms of transmission, and the testing for possible confounders.

3.2 Estimating Equations

In order to estimate the effect of the Jesuit Missions on contemporary outcomes, I use the following econometric models:

$$HK_{2000,ij} = \alpha + \beta d(M_{ij}) + \gamma GEO_{ij} + \mu_j + \epsilon_{ij} \quad (1)$$

$$f(Y_{2000,ij}) = \alpha + \beta d(M_{ij}) + \gamma GEO_{ij} + \mu_j + \epsilon_{ij} \quad (2)$$

³⁷To the best of my knowledge, no comparable information exists for Argentina at the municipal level for the area studied. Note, for instance, that neither the World Values Survey nor the regional Latinobarometer sample the areas under consideration.

³⁸Some of the variables are not available for all countries, so are complemented with similar indicators, such as income data with poverty measures and median years of schooling with literacy.

³⁹For the specific description and units please refer to the Data Appendix.

where HK and Y are human capital and income in municipality i in state / country j in equations 1 and 2, respectively.⁴⁰ M measures missionary presence at the municipality level and the d function is either a missionary dummy or distance to the nearest mission in kilometers. Hence the coefficient of interest is β which in the case of a positive effect would be positive in the dummy formulation and negative in the distance to the nearest mission formulation. GEO is a vector of geographic and weather controls with a corresponding vector of coefficients γ . μ captures a country or state-fixed effect, depending on the specification. α is a generic constant and ϵ is an idiosyncratic error term. I use a similar formulation to Equation 1 when I analyze cultural outcomes.

3.3 Estimation

To actually estimate the equations above, I use OLS with fixed effects. Controlling for fixed factors is important for several reasons. Data collection might vary at the country and even the state level. There can also be national institutional differences that are important to take into account in the estimation (Acemoglu et al. 2001 and 2002). I use robust standard errors throughout, except when the number of observations is too small and I jointly report bootstrap standard errors. Given the small number of countries and states I do not cluster errors at this level, but instead conduct robustness tests using spatially adjusted Conley standard errors (results not shown).⁴¹ As an exception, I use OLS and probit specifications with errors clustered at the district level for the individual level data in the cultural section. I report results for both the full and reduced samples at different distance thresholds (<400, 200 and 100 kilometers from the nearest mission) in order to reduce the constraint imposed by modern administrative boundaries. The results are preserved and appear stronger at the local level.

3.4 Identification

The causal identification of the missionary effect hinges on several assumptions. First, the historical record suggests that the foundation of the missions proceeded in a relatively haphazard manner.

⁴⁰As is standard, I take the logarithm of income.

⁴¹In particular, I use alternative cutoffs of .1, .5 and 1 degrees, which reduce the standard errors slightly but leave the general significance levels unchanged.

Hernández (1913) describes as a “coincidence” the entrance of the Jesuit priests to Paraguay. Other historians describe the foundation of San Ignacio de Guazú as an unprecedented “adventure” and the initial establishment of the first missions as “perilous and random” (Astrain, 1996). The remarkable success of some missionaries is contrasted with the failure and even death of some of their contemporaries. Priests like Antonio Ruíz de Montoya, were very successful in founding several missions, while others like Diego de Alfaro and Alfonso Arias died trying. I also control directly for geographic conditions such as lower altitude and proximity to rivers that might have influenced the initial settlement choices.⁴² Since Jesuit missionaries might have chosen places with more favorable geographic conditions, it is important to include these variables directly in the estimation. Moreover, being the last Catholic order to arrive to the Americas, the Jesuits had last pick and ended up in peripheral areas of the Portuguese and Spanish empires. This issue will be examined further in the section contrasting Jesuit and Franciscan missionaries. Finally, I use standard econometric techniques such as placebo tests (abandoned missions) and instrumental variables (exploration routes and historical border changes) to confirm the causal effect of the Jesuit missions. I discuss the possible issue of sorting in relation to geography, migration and urbanization throughout the paper. I do not find that selection is driving the Jesuit missionary effect.

4 Main Results

The main results of the paper can be divided into three sections. The first one shows that missionary districts have approximately 15% more years of schooling and higher literacy levels in both modern and historical time periods. The second shows that these differences in education have translated into higher incomes or lower levels of poverty of around 10%. I also present a placebo test (abandoned missions) to tackle the potential endogeneity of missionary location. The third and last section looks at differences in non-cognitive skills and preferences, using experimental evidence.

⁴²In the robustness section, I show that the Jesuit areas do not have higher population densities in modern and pre-colonial times.

4.1 Human Capital

4.1.1 Raw Data

Before running any regression, Figure 5 summarizes the spirit of this section. The graph plots modern literacy rates for people aged 15 and older versus distance to the nearest Jesuit mission in kilometers. Municipalities that had missions (orange triangles) cluster at the left hand upper corner with rates above 90%. It appears with the linear trend line that the farther away a municipality is from a historic mission, the lower its literacy level. This unconditional relationship is negative and highly significant with a t-statistic of -4.36. Although literacy rates are relatively high and have converged in modern times, the negative relationship appears substantial. To better quantify this phenomenon I estimate Equation 1 using median years of schooling for Brazil and literacy rates in the merged sample. The pattern observable in the raw data is confirmed in the regressions.

4.1.2 Median Years of Schooling

As a proxy for human capital, I use first Brazilian data on median years of schooling.⁴³ In order to capture the missionary effect I use distance to the nearest Jesuit mission. The results of estimating Equation 1 using this variable and the distance formulation can be seen in Table 3.⁴⁴ The coefficients are negative, strongly significant and stable in the full and localized samples of 400 and 200 kilometers to the nearest mission.⁴⁵ With a mean of around 5 years of education, the estimates suggest that moving 100 kilometers closer to a mission increases years of schooling by .6 to .8 years or around 15%. So these magnitudes are economically important, especially when considering that Brazil has a low level of education, even by Latin American standards (Hanushek and Woessmann, 2012). The results are also in the 10% ballpark of educational benefits of the *Bolsa Familia* conditional cash transfer program (Glewwe and Kassouf, 2012).

⁴³This information is not available for Argentina or Paraguay.

⁴⁴I control directly for geographic and weather characteristics in the estimation.

⁴⁵For Brazil, less than 400 kilometers covers less than 90% of the sample and less than 200 kilometers about half of the sample.

4.1.3 Literacy

As a second proxy of human capital I use literacy rates, which are reported for the three countries. Merging the data and running the human capital specification with state fixed effects leads to similar conclusions as before. The point estimates are positive and significant for illiteracy rates (Table 3). The coefficients are stable and increase in magnitude in the local sample. With a mean literacy rate of around 90%, the effect estimated suggests a reduction in illiteracy of at least 10% when moving 100 kilometers closer to a mission. Again the missionary effect on education is notable given the different historical and institutional trajectories of Argentina, Brazil and Paraguay.⁴⁶ Overall, I find there to be a positive and significant effect of Jesuit Missions on modern human capital, measured as median years of schooling in Brazil and illiteracy for all of the three countries. The education results are comparable and slightly larger than the ones found by Nunn (forthcoming) for Christian missions in Africa.

4.1.4 Intermediate Historical Outcomes

I examine intermediate human capital outcomes for two reasons. First, to see how the effects I find for the modern time period have been accumulated differentially over time. Additionally, the historical data can also be used to identify heterogeneous effects. I focus on the Argentinean Census of 1895 and the Brazilian Census of 1920, though the results also hold for alternative years for these countries and for the Paraguay 1950 Census.⁴⁷ In general, I find that Jesuits had an even larger effect on human capital during intermediate historical periods.

Table 4 presents the results for the 1895 Argentinean census. Illiteracy appears consistently higher the farther away the municipality is from a Jesuit mission. The results are not only positive and significant but also larger than before (Column 1).⁴⁸ Being 100 kilometers closer to a mission leads to a reduction in illiteracy of 4%. The larger effect might be due to the much lower levels of literacy

⁴⁶For robustness, I also estimate the literacy formulation in the merged sample using distance to the nearest mission for each country (not shown). This leaves the results unchanged only reducing slightly the magnitude of the coefficients.

⁴⁷These are the Argentinean Census of 1914 and the Brazilian Census of 1940.

⁴⁸Due to the small number of observations, I also report bootstrap standard errors.

during this period, which had an average of 23% and a standard deviation of 8%. Alternatively, the missionary educational treatment might have faded away over time, so it is not surprising to see a stronger effect in the past.⁴⁹

In terms of heterogeneity, the results are higher for females than males (Columns 2 and 3). Furthermore, they also appear concentrated among Argentineans as opposed to foreigners (Column 4).⁵⁰ This is sensible, as the first were largely the descendants of those who received the missionary treatment, while the second had only recently arrived to the country.⁵¹ The heterogeneous findings are also consistent with a story of vertical cultural transmission (Cavalli-Sforza and Feldman, 1981; Boyd and Richerson 1985; Bisin and Verdier 2000 and 2001) for the historical period.

The results for the 1920 Brazilian census are very similar to the ones just described for Argentina.⁵² The effect on literacy is statistically significant and large for the Brazilian population as a whole (Table 4, Column 5) and for different age groups: 7 to 14 years and over 15 years of age (Columns 6 and 7). Results are much larger for the second group. As for Argentina, the effect is also larger historically, in the order of 10%, and again it appears concentrated on Brazilians as opposed to foreigners (Column 8).⁵³

Additional results show a large degree of persistence between historical and modern levels of literacy (Figure 6). This is especially true for Argentina, with a slope of .23, but also holds for Brazil, albeit with a higher degree of convergence with a slope of .193. A similar exercise with the 1950 Paraguay data reveals a slope of .217. All relationships are statistically significant at the 1% level. Though striking in itself, this degree of historical persistence is not surprising if one considers the earlier results for the missionary period. Indeed, one interpretation of the intermediate historical

⁴⁹It is well known that literacy levels have converged during modern times (Hanushek and Woessmann, 2012).

⁵⁰These results also hold when using the 1914 census (not shown). Using that census I find additionally that missionary areas have higher levels of educational instruction.

⁵¹Recall that this was an age of mass migration to Argentina (Droller, 2012). The issue of migration in modern times is explored in the robustness section.

⁵²Since the data are reported for different age groups and for incomplete literacy (read not write and vice-versa), I keep here the complete literacy variable instead of using its complement. To make the samples comparable, I restrict the Brazilian sample to municipalities 200 kilometers or closer to a historic mission.

⁵³The literacy results also hold for the 1940 census, not shown. This census allows for the estimation of educational instruction as an alternative educational variable.

results is that the missionaries altered the early levels of human capital, generating differences in accumulation that were observable during historical times and are prevalent even today.⁵⁴ In the next section I examine whether these educational differences have been translated into differences in income.

4.2 Income and Poverty

4.2.1 Nighttime Satellite Data

A first way to illustrate the impact of the Jesuit Missions on income is through the usage of nighttime satellite data (Henderson et al. 2012).⁵⁵ From outer space, the missionary area is depicted in Figure 7, along with municipal level boundaries. As can be observed, many of the light spots associated with higher income correspond to the historical placing of the Jesuit missions. Note that the missions are still in very isolated areas, far away from the main population centers (Figure A.4).⁵⁶ I only use the nighttime satellite data for illustrative purposes, due to the availability of more reliable income and poverty measures for the countries studied.⁵⁷

4.2.2 Per Capita Income

The results of estimating Equation 2 using the the distance formulation for income can be seen in Table 5 (first three columns) for Brazil.⁵⁸ All specifications include geographic and weather controls. The coefficients appear negative and strongly significant in the full sample (Column 1)

⁵⁴A similar argument has been made by Rocha et al. (2013) for the European colonies in the state of São Paulo, Brazil. As will be seen in the Persistence Mechanisms section, this view is also consistent with Botticini and Eckstein (2005, 2007 and 2012) in that an early human capital shock resulted in long-lasting differences in occupational structures.

⁵⁵I thank Ömer Özak for suggesting this point.

⁵⁶I test directly for this possibility in the robustness checks.

⁵⁷For example, Michalopoulos and Papaioannou (2013) use nighttime satellite data due to the lack of reliable GDP per capita and income measures for the African continent.

⁵⁸I explore alternative formulations in the Appendix. This variable has several advantages over the dummy formulation. First, as a continuous variable it provides a more informative and flexible measure of missionary intensity for municipalities that did not have a mission within their border. Second, it helps to solve the problem that missions might not have had such clearly-defined boundaries over time, cf. Dell (2010), where the *mita* boundaries were strictly drawn and enforced in Bolivia and Peru. Additionally, people might have migrated to nearby towns or vice versa, an issue I explored explicitly in the intermediate historical results and retake in the robustness checks.

and remain robust in the reduced samples (next two Columns). Being 100 kilometers closer to a mission brings a maximum of .3 log points of income per capita.

4.2.3 Poverty: Unsatisfied Basic Needs Index

Because of the lack of income data at the municipal level for Argentina and Paraguay, I study these two countries separately using instead the Unsatisfied Basic Needs (UBN) Index as a multidimensional measure of poverty.⁵⁹ The results can be seen in Table 5, using the continuous distance to the nearest mission formulation and country fixed effects.⁶⁰ The results appear very similar to the ones for Brazil. The coefficient for distance to the nearest mission now emerges significantly positive (since the dependent variable is now poverty) in Column 4. I further reduce the sample to places 100 kilometers away from a mission.⁶¹ Again the point estimates are stable and effects appear larger at the local level (Column 5). By construction, the poverty index allows for an easier interpretation of the results. In terms of magnitude, as one moves 100 kilometers farther away from a missionary district, the poverty index increases by approximately 10%. The results are also robust to using the household as opposed to the person UBN index, in the last two columns of Table 5. The comparable results for countries with marked historical and institutional differences point toward the strength of the Jesuit effect on income.⁶²

To assess the economic importance of the human capital results, I run a specification of income on literacy, instrumented by distance to the nearest Jesuit Mission (not shown). The unconditional estimates are of around 27% while the ones with geographic and weather controls are of around 8%, which is consistent with micro evidence (Psacharopoulos and Patrinos, 2004) as discussed in Acemoglu et al. (2014). The results suggest the importance of controlling for these variables in the

⁵⁹The UBN methodology seeks to determine, with the help of a few simple indicators, if the population's basic needs are being satisfied. The groups that do not reach the minimum threshold are classified as poor. The selected simple indicators are: inadequate housing, housing with critical overcrowding, housing with inadequate services, households with high levels of economic dependence, and households with school-age children not enrolled in school. The UBN index is normalized from 0 to 100.

⁶⁰Again, all specifications control for geographic and weather characteristics.

⁶¹I use this cutoff for the Argentina and Paraguay sample since less than 200 kilometers covers around 90% of the observations and less than 100 kilometers around 70% of the sample.

⁶²I explore alternative specifications in the Appendix.

estimation. But could the observed difference be driven by other factors, beyond these observable characteristics?

4.3 Placebo Test

Jesuit missionaries might have sorted into better places, beyond observable geographic and weather characteristics. In order to address the endogeneity problem of missionary location I conduct a placebo test. In particular, I look at missions that were initially founded but abandoned early on by the Jesuits. This goes to the heart of the question as to whether Jesuits simply picked better places *ex ante*.

4.3.1 Abandoned Missions

The Guarani missions were not the only ones founded by the Jesuits in the Guarani area. Three nearby missionary nuclei were established by the Jesuits in Guayra, Alto Parana and Itatin. These missions all belonged to the exploratory period lasting for 50 years until 1659. In the Guayra region the Jesuits founded Loreto and San Ignacio in 1610; and in Alto Parana they founded the missions of Nuestra Señora de la Natividad de Acaray in 1624 and Santa María la Mayor de Iguazú in 1626. In the Itatin region they founded several reductions the last of which was Yatebó in 1634. These missions were abandoned early on and were not integrated with the rest of the Guarani system of missions (Hernández, 1913).⁶³ The Guayra foundations lasted from 1610 to 1630 and the Alto Parana nuclei from 1609 to 1638. Itatin foundations were disbanded in 1648 and finally relocated in 1659.

The principal threat to the survival of these missions was their proximity to the Portuguese bands of slave hunters or *bandeirantes* (Ganson, 2003). The *bandeirantes* attacks started in 1611 and intensified from 1628 to 1632.⁶⁴ Father Diego de Alfaro was killed by the Portuguese in 1637 Garruchiños and Alfonso Arias in 1645 in Itatin (Hernández, 1913). The Guarani area

⁶³Jesuit Domingo Muriel provides a valuable contemporaneous account of these missions (reprinted in Furlong, 1955).

⁶⁴The effect of the *bandeirantes* will be explored further in the Appendix using an IV strategy. In general, I do not find a direct long-term effect of these raids.

would remain prone to attacks, as evinced by the *bandeira* of Francisco Pedroso Xavier in 1676. The *bandeirantes* were not the only threats to the consolidation of missions, which also depended critically on the survival of priests. The missionaries were working in a context of hardship and low levels of recruitment. In fact, the early years of 1650-1655 are described as the worst in terms of Jesuit recruitment to the New World (Galán García, 1995). At the same time, Jesuit priests faced difficult circumstances and even death in the apostolic front lines, especially during the early exploratory period. In 1628 the Jesuit martyrs Roque González, Alfonso Rodríguez and Juan de Castillo were killed by natives in the area of Ijuí (Hernández, 1913). A similar fate was suffered by Cristovão de Mendoza in Caixas do Sul in 1632 and by Pedro Romero in Santa Barbara in 1645. Such deaths were critical blows to fledging missions, which counted only one or two Jesuit priests.

I retrieve the coordinates for the abandoned missions of Guayra, Alto Parana and Itatin to use them as a placebo test. The rationale of this exercise is that these places were also picked originally but abandoned early by the Jesuits, so they did not receive the full missionary treatment of the Guarani missions. In the absence of a grand plan for the construction of the Jesuit Missions, these abandoned establishments are as close as I can get to unbuilt missions (see for instance, Greenstone et al. 2010 and Michaels 2008).

I find no effects for the abandoned missions, either in terms of education or income. For literacy (Table 6, Columns 1 to 4), some of the coefficients are significant separately but appear now with the opposite (positive) sign. When estimated jointly, they lose significance or do not appear with a consistent sign. As can be seen in the last four Columns of Table 6, the coefficients for income for the missions of Alto Parana, Guayra and Itatin are not significant either separately or jointly.⁶⁵ The results do not support the hypothesis that the *bandeirantes* had a negative and long-lasting effect in these areas.⁶⁶ The findings in this section suggest that it was not just the original placement of missions but the actual development of the missionary activities for centuries which

⁶⁵The Guarani Jesuit distance results are robust to the inclusion of these abandoned missions (not shown).

⁶⁶To test for this possibility I run a specification with direct distance to Villarica, which was attacked repeatedly by the *bandeirantes*.

had an effect in the long-term.⁶⁷ Endogeneity issues aside, did the Jesuit missionary treatment lead to differences in other outcomes besides human capital and income? To answer this question I present evidence from a household survey.

4.4 Experimental Evidence

Formal education is not the only aspect of human capital formation that can impact economic outcomes in a major way (Heckman and Rubenstein 2001 and Heckman et al. 2006). Non-cognitive skills may have similarly benefitted from the Jesuit “intervention” and norms of cooperation may have changed in a differential fashion. In order to take a more in-depth look at individual level behavior and attitudes in the missionary area, I conducted a household-level survey in Southern Paraguay (Figure 3).⁶⁸ The survey covered all the eight Paraguayan Jesuit missionary districts (in blue) and sampled 12 comparable districts (red dots) in the states of Misiones, Itapúa, Caazapá, Guayrá and Alto Paraná.⁶⁹ Within the twenty villages, 28 household heads were randomly selected to complete the interviews.⁷⁰ The survey focuses on cultural questions, following recent contributions by Falk et al. (2014), as well as standard questions from the World Values Survey and the regional Latinobarometer equivalent.⁷¹

As a measure of non-cognitive skills I use the Rotter Locus of Control (Heckman et al., 2006). This psychological test categorizes a respondent’s attitude on a scale going from purely external (low) locus of control (“destiny is predetermined”) to the exact opposite (“I alone control my own destiny”). There is a significant difference between average responses in Jesuit missionary and non-missionary districts (Figure 8). Not only is the whole distribution shifted to the right (internal

⁶⁷Another way to explore this issue is to look at the intensity of treatment effects of Jesuit Missions, which I present in the Appendix of the paper.

⁶⁸I gratefully acknowledge the financial support from Zurich University for this project. I also thank Gharad Bryan, Rosemarie Nagel and Laura Schechter for very helpful comments. This is the first tranche of a project that plans to cover also the Jesuit missionary areas in Argentina and eventually Brazil.

⁶⁹Comparable districts were selected on the basis of their population and income. The survey was carried on by E+E Economía y Estadísticas para el Desarrollo, a local Paraguayan consulting firm.

⁷⁰First blocks were randomly selected using maps from each of the districts. Starting from a randomly chosen household, the enumerator proceeded to interview the third house of each block going counter-clockwise. Depending on the size of the block three to four households were selected in each block. All participants were rewarded with a notebook of 1 dollar value for their participation.

⁷¹The actual text of the survey is available upon request.

locus of control) for the Jesuit districts, but the difference is statistically significant at the 5% level (Table 7, Column 1). Standard errors are now clustered at the district level.

Another goal of the survey was to determine whether there were significant differences in terms of preferences and social norms between the missionary and non-missionary areas. To this end, I conduct standard games from the psychology and experimental economics literature including dictator and trust games, as well as questions on time discounting and risk preferences.⁷² The results of these exercises are presented in Table 7. Residents in Jesuit missionary areas are markedly more altruistic (Column 2) in a hypothetical game of allocating 1 million Guaranis (220 Dollars or two week's wages). I also find that these respondents are more willing to allocate money received in a trust game, a measure of positive reciprocity, in Column 3.⁷³ There seem to be no significant differences in terms of time discounting (Column 4), but less willingness to take risks.⁷⁴ This can be seen in the higher certainty equivalence required from a 50-50 lottery of 0 or 1 million Guaranis (Column 5).⁷⁵

I also conduct a cheating game with the respondents, in the spirit of Hanna and Wang (2013) and Lowes et al. (2014). In the game individuals tossed a fair coin nine times. They were told *ex ante* to count the number of heads they will get and that with five or more heads they would obtain an extra compensation for their participation (a box of tea, a traditional staple food with a one dollar value).⁷⁶ In the sample as a whole, there is evidence of dishonesty – 359 people (64%) claim to have obtained 5 or more heads versus 201 that report 4 or less.⁷⁷ There are also important differences between the missionary and non-missionary areas (Table 7, Column 6). In the latter, more people seem to be lying, claiming that they obtained more than 4 heads.

⁷²For the specific questions please see the Data Appendix.

⁷³Results are robust to using the 5,000 transfer for a total of 25,000 Guaranis to be redistributed.

⁷⁴Note that some of the responses are bounded to correspond with the wording of the question, leading to a decrease in the number of observations.

⁷⁵Results are robust to using constructed measures of risk preferences (lover, neutral and averse) from this answer.

⁷⁶In particular, respondents were told that they would receive as compensation a notebook (of one dollar value) and depending on the response from this game an additional box of tea (also of one dollar value).

⁷⁷This familiar pattern is consistent with the findings of Fischbacher and Föllmi-Heusi (2013). As is standard, we do not know for a fact whether people cheated in this experiment, only through the deviations from an even split. We also made sure that enumerators did not observe or record the outcome of this section, leaving the respondents to write their own responses.

The survey strongly suggests that long-term benefits of missionary activity are not limited to higher levels of formal education. In addition, there is substantial evidence that inhabitants in areas where Jesuit missions existed are more honest, trust each other more, and reward each other for cooperative behavior to a greater extent. They are also more risk-averse. One obvious question to ask is if this is possibly driven by persistent levels of religiosity, along the lines of the “Big Gods” argument (Norenzayan 2013; McKay et al. 2014). To examine this mechanism further, I use religious priming to examine if it affects collaborative behavior.

Respondents were asked about their religious beliefs and religious practice as part of the survey. This question was administered either right before or right after the experimental section, based on random assignment. There appear to be no significant differences in terms of preferences (results not shown). Only the coefficient for certainty equivalence is positive significant at the 10% level, but the magnitude is five times smaller than before. There are no significant differences in the cheating game either. It does not seem that religious priming is driving pro-social behavior. Or put differently, that the differences in responses are due to fundamental or structural differences and not to very short-term interventions.

5 Empirical Extensions

In this section I present empirical extensions and alternative estimations of the main results described so far. First, I compare Jesuit with Franciscan Guarani Missions, which did not stress education in their conversion. I also present instrumental variables strategies as an alternative to tackle the potential endogeneity of missionary location. The IV results are broadly consistent with the OLS estimates.

5.1 Franciscan Guarani Missions

The study of Franciscan Guarani Missions allows for the comparison between two Catholic orders with a different focus in a similar area. Was it the establishment of missions in the Guarani area

or the focus that they had which led to differential outcomes in the long run? The comparison with the Franciscan Guarani Missions is a relevant one, as many of the elements that led to their location—such as indigenous availability, favorable climatic and geographic conditions—were common to the Jesuit Missions. Ultimately, both Catholic orders wanted to maximize the number of souls converted to Christianity. However, the Franciscans did not stress human capital formation and technical training in their conversion.

Jesuits were not the first to establish religious missions in the Guarani area (Figure 4). The first Guarani Franciscan Missions were established between 1580 and 1615 by Fathers Bolaños and Alonso, while the first Guarani Jesuit Mission appeared in 1609 (Durán Estragó, 1987). By choosing first, Franciscans located themselves further north and closer to the existing population centers, presumably ending up in better locations. I study the early missions of Altos founded in 1580, Itá in 1585, Yaguarón in 1586; Atyrá, Guarambaré, Tobatí and Ypané from 1580 to 1600, Caazapá in 1606, and Yuty in 1611. I use the exact location and the available historical population data for these Franciscan Guarani Missions.

One way to see the differences between Jesuit and Franciscan Guarani Missions is by using contemporary population data. Figure 9 shows the mean population in both sets of missions from 1640 to 1760. Though the data series is incomplete, the divergence between Jesuit and Franciscan missions is apparent (Maeder, 1995).⁷⁸ Starting from a similar base of around 1,500 people, Jesuit Missions reached almost three times that number at their peak in 1730. By comparison, Franciscan missions remained fairly stable in terms of population, declining from 1720 onward. In a Malthusian regime, these differences in population can be interpreted as early differences in income (Galor and Weil 2000; Ashraf and Galor 2011; Galor 2011).

Second, I test directly whether Franciscan missionaries had the same effects as Jesuits in the long term, by re-estimating the human capital and income equations, using instead distance to the nearest Franciscan mission. The results, or lack thereof, can be seen in Table 8. I find no effect for

⁷⁸Even when they were devoted to similar activities (cattle raising and *yerba mate* cultivation), the Jesuits proved more effective (Maeder, 1995).

either modern literacy or income (Columns 1 and 2). Franciscans might have picked geographically advantageous places, but the effect of their missionary treatment does not appear to be long-lasting. In a horserace between the missions from the two orders I find that the beneficial effect on education and income is preserved for the Jesuits and appears now negative for the Franciscans (Columns 3 and 4). Even though the two variables are highly correlated, so it is hard to take these results at face value, it is still worthwhile to analyze what could be driving the disparities.

First there is a difference in terms of focus. As has been argued before, from the outset there was a clear emphasis on human capital formation and technical training on the part of the Jesuits, a difference that prevails today. The mendicant orders, to which the Franciscans belonged, were characterized since their inception by tending for the sick and the poor, charity and reducing inequality. “The Jesuit order, in contrast [to the Mendicant orders], was not defined by its commitment to poverty and to the poor.” Waldinger (2013, p. 2). In the last two columns of Table 8 I examine this possibility.⁷⁹ Areas closer to Franciscan missions do not seem to have lower levels of inequality relative to the Jesuit areas (Column 5). The same is true for health, proxied by mortality (Column 6). If anything, the Jesuit areas do better in these regards. It is the Jesuit focus on human capital, which appears to have had a beneficial role in the long run.⁸⁰

5.2 Instrumental Variables

An alternative way to address the potential endogeneity of Jesuit missionary placement is to use standard instrumental variable techniques (Angrist and Pischke, 2008). The idea is to find a source

⁷⁹To see how the mendicant character of some Catholic orders actually benefited human capital formation in the case of Mexico, see Waldinger (2013). Another distinction between the two scenarios is that the Jesuits focused more on elite education in Mexico relative to Paraguay, where the missions took the lion’s share of their apostolic efforts.

⁸⁰Other differences between the Franciscan and Jesuit Missions have been documented in the historical literature. Institutionally, Franciscans were more open towards the colonial labor system of *encomienda*, while Jesuits were more successful in obtaining lower labor tributes and taxes from the Spanish Crown (Salinas, 2010). An exception being the Jesuit Mission of San Ignacio de Guazú which was located closer to the Franciscan Missions and experienced the *encomienda* labor regime. Also, by choosing first, Franciscans located themselves further north and closer to the existing population centers, which made it harder for them to resist the Spanish colonial encroachment. For instance, indigenous people from these missions were used to execute local works (Salinas, 2010). The isolation of the Jesuit Missions in what were essentially frontier lands made it harder for the Spaniards to use the natives for such activities, protecting and benefiting them in the long term.

of variation that is correlated with the initial placing of the missions, but that does not affect the outcomes of interest directly. In this section I present two such candidates: original exploration routes and distance to Asuncion. I provide some historical background to justify these choices and examine their corresponding exclusion restrictions.

5.2.1 Exploration Routes

As has been stressed before, Jesuit missions were located in remote areas of the Spanish and Portuguese colonies that remain relatively isolated even today. The aim of this section is to capture a measure of isolation that can be used to proxy for missionary location. One such candidate is distance from early exploration routes (Figure 10). Historical exploration routes such as Lewis and Clark's in the US have been recently used as instruments for highway development (Duranton and Turner 2012; Duranton et al. 2014). For the missionary area the equivalent are the expeditions of Pedro de Mendoza (1535-1537) and Alvar Nuñez Cabeza de Vaca (1541-1542).

Under the aegis of the Spanish Crown, Pedro de Mendoza explored the Río de la Plata (River Plate) region of South America (Figure 10). Sailing from Spain and the Canary islands and following the delta of the River Plate, he founded the city of Buenos Aires in 1535 (Figure 4). Mendoza became the first Governor of the Río de la Plata region, but died shortly thereafter from syphilis in 1539 (Chipman, 2014). From Buenos Aires, lieutenant governor Juan de Ayolas sailed almost 1,000 kilometers up the Paraná River and founded the fort of Corpus Chirsti in 1536. Similarly, interim governor Domingo de Irala founded Nuestra Señora Santa María de la Asunción (Asuncion) in 1541.⁸¹

Alvar Núñez Cabeza de Vaca, who became famous for his conquest of Florida and the Gulf of Mexico, also played an important role in the exploration of South America (Chipman, 2014). Cabeza de Vaca was given permission to explore the Río de la Plata region in 1540 (Figure 10). He started off in the island of Santa Caterina (modern/day Brazil) and instead of sailing to Buenos Aires took the fateful decision to traverse the interior and walk barefoot more than 1,200 kilometers

⁸¹Distance to Asuncion will be explored as an alternative instrument in the next section.

to Asuncion. After four and a half months of traversing “a trackless wilderness filled with cannibals, impassable rivers, jungles and poisonous snakes” (Chipman, 2014, P. 54) he arrived to Asuncion the morning of March 11, 1542.

The rationale of the instrumental strategy is to proxy for the remoteness of the Jesuit missions using distance from the expedition routes (negative first stage). These routes served to found the initial cities, whereas the missionary area remained relatively unexplored. At the same time, the exact path of the expeditions was somehow arbitrary. The results of instrumenting missionary location with distance to the exploration routes can be seen in Table 9. The first stage is negative and significant (F-statistic well above 10). The second stage results are positive for illiteracy (Column 1) and negative in the income formulation (Column 5), as before. The magnitudes are similar for education and slightly larger for income.

5.2.2 Distance to Asuncion

As was mentioned in the historical context, the first Jesuits arrived in Asuncion on the 11th of August of 1588 (Figure 4). From that base, Fathers Manuel Ortega and Thomas Fields started their evangelical expedition in the territory of Guayra. Subsequent expeditions explored the area controlled by the Guarani, leading to the foundation of the first mission of San Ignacio Guazú in 1609. Asuncion would remain an exploratory base throughout the missionary period (Figure 11). Still, it is important not to overemphasize the importance of Asuncion, which had a population of 6,451 in 1761, twenty times less than the Jesuit Missions (Ganson, 2003).

In 1750, less than twenty years before the expulsion of the Jesuits, the Treaty of Madrid changed the Spanish and Portuguese borders in South America. This treaty replaced the Tordesillas Treaty of 1494, largely leaving the territory of Brazil in its current form.⁸² In the missionary area, the modern state of Rio Grande do Sul passed to Portuguese hands along with the seven missions (also known in Portuguese as the *sete povos*) of São Borja, São Luiz Gonzaga, São Nicolau, São Miguel,

⁸²The San Idelfonso Treaty of 1777 would confirm the 1750 boundaries. The Tordesillas treaty will be used as an alternative instrument in the Appendix.

São Lourenço Martir, São Joao and Santo Angelo. The center of influence for this region shifted abruptly from the Spanish to the Portuguese empire, diminishing the importance of Asuncion as a colonial capital. My working assumption is that this city is even less relevant for Rio Grande do Sul in modern times, but that it was influential in the historical placing of the Jesuit Missions.⁸³

I instrument distance to the nearest Jesuit Mission using distance from Asuncion, only for the Brazilian subsample of the data (Figure 11). This identification strategy is similar to the one employed by Becker and Woessmann (2009) with distance to Wittenberg and Dittmar (2011) with distance to Mainz. I exclude the states in Paraguay given the importance of the national capital and Argentina, which remained part of the Spanish Empire after the borders were changed in 1750, until it became independent in 1810. For robustness, I control directly for distance to São Paulo, which became the new pole of influence for the region. The results of this instrumental variables exercise can be found in Table 9. The first stage is very robust (F-statistic > 10). The instrumented coefficients appear significantly positive for illiteracy (Column 2) and negative for income (Column 6). The coefficients for education appear slightly larger and the ones for income have a similar magnitude to the OLS results.

By and large, the instrumental variable results confirm the OLS results for income and education. Taken together with the placebo results, they suggest a causal effect of the Jesuit Missions on income and education. The results for exploration routes and the distance to Asuncion specifications are broadly similar though slightly larger in magnitude than the OLS results. It does not seem that this is caused by weak instruments or by the difference in samples. Beyond measurement error, this might be due to differences between average and local treatment effects due to heterogeneous effects (Imbens and Angrist, 1994 and Heckman, 1997). In the Appendix, I extend the IV analysis using distance to the Tordesillas line as an alternative instrument.⁸⁴ Beyond identification, what transmission mechanisms can be driving the observed differences?

⁸³Despite being a neighbor, Paraguay is not among the main trading partners of Brazil and its trade share (exports plus imports) was less than 2% in 2010.

⁸⁴I look at alternative estimations and intensity of treatment effects in the Appendix.

6 Persistence Mechanisms

This section presents particular occupational and cultural mechanisms that can be behind the persistent human capital and income differences observed. Guiso et al. (2006) define culture as “those customary beliefs and values that ethnic, religious, and social groups transmit fairly unchanged from generation to generation” and Nunn (2012) argues that “culture is an important mechanism that helps explain why historical shocks can have persistent impacts.” Theoretically, historical and cultural factors can affect modern outcomes through path dependence in models of multiple equilibria (Nunn, 2007 and Guiso et al. 2008).⁸⁵ Models dealing explicitly with cultural diffusion have been developed by Bisin and Verdier (2000), Doepke and Zilibotti (2008) and Mokyr (2010), among others. Empirical contributions include Fernández (2010), Alesina et al. (2013) and Atkin (2014). I focus here on the persistence of occupational structures, inter-generational knowledge transmission and indigenous assimilation. To this end I use information from two specialized surveys: the Brazilian Cultural Module of the 2006 Municipal Survey and the Cultural Module of the 2011 Paraguayan Household Survey.⁸⁶ My setting is also unique in that I can essentially shut down the genetic mechanism. Naturally, the Jesuits did not intermarry: “Jesuits were never known to take Indian women as their concubines” (Ganson, 2003, p. 78). and the period from the missionary intervention to today is also too short to entail significant genetic changes.

6.1 Occupational Persistence

An important mechanism of transmission comes from the long-lasting transformation of occupational structures. In the spirit of Botticini and Eckstein’s studies (2005, 2007 and 2012) the idea is that individuals that attended religious missions, receiving instruction and technical training, moved away from agriculture to start a proto-artisan class. Three pieces of empirical evidence point in this direction.

⁸⁵Though in his model Nunn focuses on the impact of slavery in Africa, his distinction between equilibria with productive and unproductive activities due to colonial policies is still relevant in this context.

⁸⁶Special thanks to Yolanda Barrios, Norma Medina and Zulma Sosa from the Paraguayan statistical office for sharing these data.

First, the Brazilian cultural survey asks specifically about the prevalence of handicraft activities. Embroidery was one of the activities in which the Jesuit missionaries trained the natives. Father Antonio Sepp, S.J., (1655-1773) describes in his letters the role of the workshops and how he instructed the natives to copy Dutch lace and embroidery (Amable, 1996, p. 58). In the state of Rio Grande do Sul the most important handicraft today is precisely embroidery, which results are presented in Table 10.⁸⁷ Surprisingly, hundreds of years after the Jesuit expulsion, missionary areas report more prevalence of this activity (Column 1). The empirical results are robust to the inclusion of geographic controls and larger at the local level (not shown). More generally, in the missions, “Full-time craftsmen included blacksmiths, carpenters, statuary artisans, gilders, silversmiths, tailors, hat makers, and bronze fabricators such as bell makers” (Crocitti, 2002, p. 9).⁸⁸ The long term effect of technical training is consistent with Botticini and Eckstein (2005, 2007, and 2012), where early human capital accumulation helped to consolidate a Jewish merchant and artisan class. A complementary interpretation is that embroidery could serve as a proxy for non-cognitive skills such as patience, consistent with the experimental evidence.⁸⁹

I also examine the broader occupational structure of Paraguay. Because the data is at the individual level, I employ a probit specification with state fixed effects and errors clustered at the district level. In Table 10, it is evident that the areas closer to Jesuit Missions have moved away from agriculture to manufacturing and commerce (Columns 2 to 4). This structural transformation towards more productive activities is notable in an area that continues to be predominantly rural. There is an inextricable link between human capital investment decisions and occupational choices, as in Doepke and Zilibotti (2008).⁹⁰

One last interesting source of variation in labor patterns can be observed in Figure 12. The figure plots the number of people working 15 to 39 hours a week. It appears that those closer to the

⁸⁷The results also hold for other handicrafts.

⁸⁸It will not come as a surprise then that these inhabitants assimilated better.

⁸⁹I thank Joachim Voth for suggesting this point.

⁹⁰I thank Fabrizio Zilibotti for suggesting this point. This is also consistent with the mechanism expounded before, where the portable skills transmitted to the natives might have helped to consolidate an artisan class.

missions are working more, consistent with Weberian cultural explanations.⁹¹ I find supportive econometric results for labor force participation in Brazil. It appears that more people participate in the labor force in general (Table 10, Column 5) and that this effect is concentrated among females relative to males (Columns 6 and 7). This relates back to Max Weber’s famous Protestant hypothesis. According to Weber this same ethic was found, “as early as St. Benedict [480-547], more so for the Cistercians [1098], and, finally, most decisively, for the Jesuits [1534].” (Weber, 2011, p. 130). For recent evidence comparing the thrift of these Catholic orders, see Barnebeck Andersen et al. (2013) for the Cistercian order in England and Akcomak et al. (2013) for the Brethren of the Common life in the Netherlands. Though Catholic, the Jesuits can be thought of as having the Puritan work ethic Weber underscored. In fact, he noted “The gradual rationalization of asceticism into an exclusively disciplinary method reached its apex in the Jesuit order.” (Weber, 1978, p. 1172).⁹²

6.2 Knowledge Transmission

As a specific element of cultural persistence I look directly at inter-generational knowledge transmission. This type of transmission is crucial for sustaining the persistent nature of the results shown. Though information on this topic is often neglected in standard surveys, such questions were included in the Cultural Module of the 2011 Paraguayan Household Survey. The results of this exercise can be found in Table 11.⁹³ First, I find that people in missionary areas report more knowledge of both traditional medicine and folktales (Columns 1 and 3). More importantly, they also declare having received this knowledge from their parents (2 and 4).⁹⁴ So the empirical evidence confirms inter-generational knowledge transmission as one of the cultural mechanisms behind the persistent outcomes observed.

⁹¹The relationship is statistically significant at the 1% level. A similar pattern can be observed for Paraguay, not reported.

⁹²“Just as it constituted the goal of the exercitia [religious exercises] of St. Ignatius [of Loyola, 1491-1556] and the highest forms of rational monastic virtues in general, this active self-control constituted also Puritanism’s defining practical ideal of life.” (Weber, 2011, p. 130)

⁹³I use again a probit specification with clustered standard errors at the district level.

⁹⁴It also seems that this traditional knowledge was transmitted in Spanish (results not shown), suggesting the role of differential indigenous assimilation, a mechanism I explore further in the empirical extensions section.

I also examine skills and cultural activities that are specifically related to Jesuit interventions. In particular I look at accounting, which was taught in the religious missions (Crocitti, 2002).⁹⁵ The practice of accounting emerges more emphatically in missionary areas (Table 11, Column 5). A similar result can be seen for the literacy practice of keeping a diary (Column 6) and the more general cultural habit of visiting a library (Column 7).⁹⁶ It appears that areas closer to missions have higher levels of transmitted native knowledge and imported skills. The importance of such knowledge transmission mechanisms has been stressed recently by Wantchekon et al. (2013). The long-lasting prevalence of these portable skills is also consistent with inter-generational and vertical models of transmission (Cavalli-Sforza and Feldman, 1981, Boyd and Richerson 1985, Bisin and Verdier, 2000 and 2001).

Overall, the results in this section point towards transmission mechanisms that might be driving the persistent differences in income and human capital. I see the results of occupational persistence and inter-generational knowledge transmission as cultural markers that can help to further identify the missionary treatment. I do not argue that embroidery is driving modern growth in these areas, but instead take the view that this particular skill is part of the broader technological package transferred to the indigenous people by the Jesuits. The technological transfer is even more remarkable considering that there were only one to two Jesuit fathers per mission. Ultimately, the persistence of knowledge is instrumental to understanding how income, and especially human capital, might have taken divergent paths for hundreds of years. But did these differences in know-how translated into better social integration?

6.3 Indigenous Assimilation

One last way to analyze long-term cultural behavior is to look directly at indigenous assimilation (Diaz-Cayeros and Jha, 2012). Presumably, indigenous inhabitants that attended religious missions had an easier time assimilating into the colonial society when the Jesuits left, due to the skilled

⁹⁵For a detailed account of the role of accounting in the Guarani Jesuit Missions, see Blumers (1992).

⁹⁶I obtain similar results for visits to a museum.

training they acquired. An early indication of this mechanism can be observed in the 1890 Census.⁹⁷ In Table 12 we can see that people reported more mixed marriages (general mixed and *caboclo*: European and indigenous) in places closer to religious missions (Columns 1 and 2).⁹⁸ No such question was asked in later censuses. Interestingly, they also report being more Catholic, albeit from a very high base of 93% (Column 3).⁹⁹

The prevalence of indigenous people in the missionary area can also be observed up until today. Column 4 in Table 12 reports results for Brazil. In 2010, more people report being indigenous the closer they are to a mission. This is interesting, since in Latin America areas with higher modern indigenous population density have been associated with lower levels of income.¹⁰⁰ A similar pattern can be found for Paraguay, when focusing on language. Guarani is one of the two official languages of Paraguay, along with Spanish, in itself a remarkable testament to the survival of the aboriginal tribes. In fact, linguists point directly to the religious missions for the survival of Guarani (Engelbretch and Ortiz, 1983). For empirical purposes, this also means that data on the prevalence of Guarani is recorded by the Paraguayan statistical office. The results using this data can be seen in Table 12, Columns 5 to 7.¹⁰¹ It appears that there are less people speaking Guarani in the missionary areas and more people speaking Spanish. Furthermore, there are more people who report speaking *both* languages in these areas, again suggesting a differential process of assimilation.¹⁰²

From early records of mixed marriages to contemporary data on indigenous population in Brazil and indigenous languages in Paraguay, it appears that indigenous people assimilated more in the missionary areas from colonial times up until the present day. Which other channels or mechanisms of transmission can be ruled out?

⁹⁷Given the small number of observations, I include a reduced set of geographic controls.

⁹⁸This mixing could affect the genetic composition of the population, though I still find more people that self-identify as Guarani in this area.

⁹⁹I find similar results for modern data, not reported.

¹⁰⁰The role of European population and development has been discussed in Acemoglu et al. 2002, Easterly and Levine, 2012, Putterman and Weil 2010, Chanda et al. 2014, and Valencia Caicedo and Maloney 2014.

¹⁰¹Because the data is again at the individual level, I employ a probit specification and cluster the errors at the district level. I also include state fixed effects for Paraguay, which leaves the results unaffected.

¹⁰²These results also hold using data from the 1950 census. The colloquial combination of Spanish and Guarani is termed Yopará.

6.4 Robustness Checks

In this last section, I present complementary evidence for the Jesuit effect on modern income and human capital as the main channel of transmission. I do so by exploring alternative channels and analyzing heterogeneous effects. In particular, I rule out possible confounders such as population density, migration, health and tourism.

6.4.1 A. Population Density

Perhaps one of the most obvious alternative channels of transmission of the missionary effect is population density.¹⁰³ The religious entities might just have initiated future urban agglomerations, as in Becker et al. (2010). The results of this exercise can be found in Table 13. I find, if anything, that places close to the Jesuit Missions are less dense today. The coefficient is positive and significant for the full sample (Column 1) and insignificant for the more localized sample (Column 2).¹⁰⁴ These results do not come as a surprise when collated with the historical record, since Jesuit missionaries went to peripheral areas isolated from existing population centers. Even though the Jesuit Missions thrived historically, by no means did these places become modern metropolises (as can be seen in Figure A.4). I also explore the possible prior role of pre-colonial population density in Column 3.¹⁰⁵ Data come from Maloney and Valencia Caicedo (2012) and are only available at the state level. I do not find that the states where Guarani Jesuit missions were located are denser relative to their Argentinean, Brazilian and Paraguayan counterparts. The results suggest that the Jesuits affected the people they treated more than the places they visited.

6.4.2 Migration

Although the issue of migration has been addressed before in the paper, this section focuses specifically on this possible confounder. Migration informed the empirical strategy and, in particular, the usage of the more continuous nearest distance formulation. Historically, missions grew through natural reproduction rather than immigration (Livi-Bacci and Maeder, 2004). In the interme-

¹⁰³As has been argued for Bai and Kai-sing Kung (2011) for China.

¹⁰⁴I obtain similar results for even more reduced samples.

¹⁰⁵I thank Nicola Gennaioli for suggesting this point.

diate historical results it also appeared that the human capital effect was concentrated among Argentinians and Brazilians as opposed to foreigners, but does this finding hold also for modern times?

To answer this question, I divide the Brazilian sample into municipalities with high and low mobility, namely, where people declare that they are residents or not of that municipality. Table 13 presents the results for these subsamples. It appears that the human capital results are concentrated among residents (Column 4). The results for non-residents are insignificant and smaller in magnitude (Column 5). It does not appear that people are sorting themselves into the missionary locations in modern times. If anything, there might have been historical outmigration from the area, so the results I find could be underestimates.

6.4.3 Health

I study here health as a human capital investment complementary to education.¹⁰⁶ The data availability is restricted to Brazilian municipalities. I use standard indicators such as mortality under 5 years of age and infant mortality, as well as a multidimensional health index.¹⁰⁷ I find negative and significant coefficients for the health index suggesting better health outcomes in these areas (Column 6). Moving 100 kilometers away from a mission is enough to go from a high to a fair level of health development, a sizable downgrade. Similarly, I find positive and significant coefficients for the mortality measures, indicating worse indicators the farther away from the missionary areas (results not shown).

6.4.4 Tourism

Another possible confounder of the Jesuit missionary results can be tourism. These areas might simply receive more visitors and this could explain their relative prosperity. To test for this confounder, I use data from the Cultural Module of the Brazilian Municipal Survey (2006). The

¹⁰⁶The role of health was already explored in the Franciscan comparison section.

¹⁰⁷The IFDM (Indice FIRJAN de Desenvolvimento Municipal) is the Brazilian counterpart of the UN Health Development Index (HDI). The health index includes items such as the number of prenatal visits and deaths due to ill-defined and avoidable causes.

survey asks about the prevalence of tourism-related activities in the area. Results can be found in Column 7. I find no effect on tourism when using distance to the nearest Jesuit mission. The coefficient is slightly positive (opposite sign) and insignificant. The results are not surprising given the relative isolation and inaccessibility of the places studied.

Taken together, the results in this section point towards the robustness of the missionary effect. They give additional evidence for education as the main channel of transmission for different subsamples. The results also help to rule out the possible role of confounders.

7 Conclusion

Going back to Voltaire and the controversy over the Guarani Jesuit Missions, though it is hard to measure mildness, I do find significant long-lasting effects of these religious institutions on education and income. I find a positive and significant effect of on median years of schooling and literacy, and even larger magnitudes for intermediate historical time periods. Places that are closer to historic missionary districts have incomes that are 10% higher today. The effects are larger at the local level and robust to the inclusion of geographic controls. A placebo test and instrumental variables techniques, suggest that these effects are causal. The impact is specific to missions from the Jesuit versus the Franciscan order, which did not focus on human capital and technical training. Inhabitants of former Jesuit missionary areas have higher non-cognitive abilities and exhibit more pro-social behavior. Moreover, the enduring differences are consistent with specific cultural mechanisms of occupational persistence, inter-generational knowledge transmission and indigenous assimilation. Additional robustness tests suggest that the missionary results are not being driven by migration, urbanization or tourism.

Are the observed differences important? I interpret the differences of around 10% as substantial, yet plausible. My results are consistent with those of Nunn (forthcoming) for nineteenth-century Christian missions in Africa and similar in magnitude to well-established conditional cash transfer programs such as *Bolsa Familia*. It is remarkable that these effects are still observable centuries

after the Jesuit expulsion and are present in countries with different institutional trajectories. To analyze the economic importance of my results, I run a specification of income on literacy, instrumented by distance to the nearest Jesuit Mission.¹⁰⁸ I find estimates on the order of 8%, a value consistent with micro evidence in general and the particular estimates for Argentina, Brazil and Paraguay (Psacharopoulos and Patrinos, 2004). In terms of policy, being aware of these observed differences could aid governments to better target education and labor training programs.

More broadly, the case of the Guarani Jesuit Missions serves as a microcosm to study important economic questions. I find not only an important degree of economic persistence, in line with the recent literature, but also broad channels and specific transmission mechanisms through which this persistence is enacted. In particular, I demonstrate how human capital differences can emerge in the long term leading to persistent differences in educational, economic and behavioral outcomes.¹⁰⁹ Furthermore, I document specific cultural and occupational mechanisms that can sustain these differences. The evidence in this regard suggests the salience of vertical cultural transmission.

Overall, the findings in this paper underscore the importance of particular historical events for long-term development and growth (Nunn, 2009 and 2013). I believe that such historical accidents can be instrumental in answering policy-relevant questions for which few counterfactuals exist today. This type of research can help us uncover deep-rooted factors of development. Far from advocating historical determinism, a thorough understanding of these historical forces and their implied constraints offers the opportunity to make development policies more targeted and effective.

¹⁰⁸I view this simply as a benchmarking exercise, as the potential endogeneity of missionary location has already been discussed throughout the paper. Additionally, missions might have impacted modern outcomes through other channels besides formal human capital, like culture.

¹⁰⁹Future research could further examine the behavior of individuals and firms in situ.

I. Data Appendix

In this section I provide more detailed information about the variables, units and sources used in the paper.

A. Income and Poverty

Income: Data for Brazil comes from the *Instituto Brasileiro de Geografia e Estatística* (IBGE) and can be accessed through IPEA.¹¹⁰ The data measures total annual income in 2000 in contemporary Brazilian R\$. As is standard, I take the natural logarithm of this number.¹¹¹ Comparable data for Paraguay are available from the World Bank (2008) World Development Report on Reshaping Economic Geography. The data are for mean per capita income in 2005 US dollars; for details please see Maloney and Valencia Caicedo (2012).

Poverty: Since income data are not available at the municipality level for Argentina, I instead use comparable poverty data on the Unsatisfied Basic Needs (UBN) index measured for both households and individuals. The data for Argentina are from the *Instituto Nacional de Estadística y Censos* (INDEC) for 2001.¹¹² Similar data for Paraguay comes from the *Dirección General de Estadística, Encuestas y Censos* (DGEEC) and is for 2002.¹¹³

Nighttime Satellite Images: For illustrative purposes, I use the nighttime satellite data from the F18-2010 mission, available at <http://ngdc.noaa.gov/eog/dmsp/downloadV4composites.html>. This data has been used as a proxy for income in Henderson et al. (2012), and Michalopoulos and Papaioannou (2013).

B. Human Capital

Literacy: Literacy (and illiteracy) rates are measured in percentages of the relevant population. Data for Brazil are also from the IBGE is for people aged 15 or 25 and above in 2000. Data for Paraguay come from DGEEC and are for people aged ten years and above in 2002. Literacy data for Argentina are again from INDEC for people aged ten years and above in 2001.

Median Years of Schooling: Brazil's IBGE reports data on median years of schooling for people 25 aged years and above in 2000. No similar information is reported for Argentina or Paraguay.

¹¹⁰<http://www.ibge.gov.br/home/> and <http://www.ipeadata.gov.br/>

¹¹¹Highly correlated data for municipal level GDP are also available and used for robustness only, as they tend to be less reliable than income measures at this level of disaggregation.

¹¹²<http://www.indec.mecon.ar/>

¹¹³<http://www.dgeec.gov.py/>

C. Missionary Presence

Missionary Dummy: is the simplest measure and takes the value of 1 for the municipality that had a mission historically and 0 otherwise. This coarse measure assumes that the boundaries of the missions were strict and is mostly used for descriptive purposes.

Missionary Distance: This more continuous variable denotes the closest distance between a municipality's centroid and a historical mission. It is measured in kilometers and calculated using STATA and ArcGIS. This measure is more informative and flexible with respect to missionary boundaries. A similar measure is used to study the effect of Franciscan Missions.

Missionary Population: For most of the thirty Jesuit Missions I was able to obtain historic information on the indigenous population from the Archivo General de Indias and the Roman Jesuit Archive (Vatican). Though incomplete, the records cover the period from 1650 to 1790, giving a rough picture of the contemporary conditions of the religious establishments (see Figure A.1). This measure can also be used to capture intensity of treatment effects. Comparable information is also available for some Franciscan missions.

Year of Foundation: Similarly, I obtain the year of foundation of Guarani Jesuit Missions, which can be used to calculate the number of years they was active and capture the intensity of treatment.

Mission Moved: Lastly, I construct a dummy variable taking the value of 1 if the Mission moved and 0 otherwise, again to capture the intensity of treatment effect.

D. Geographic and Weather Controls

Area: Total area in squared kilometers taken from IBGE (2010) for Brazil, and calculated with ArcGIS for Argentina and Paraguay.

Altitude: Elevation measured in meters over sea level originally available at very high resolution from WorldClim and processed using ArcGIS.¹¹⁴ Similar data are also available from IBGE (2000) for Brazil and used alternatively for robustness. Recorded separately in the household survey.

Latitude and Longitude: Measured in decimal degrees for the municipal centroid and taken from IPEA (2000) for Brazil, and calculated with ArcGIS for Argentina and Paraguay. Recorded separately in the household survey.

Temperature: Annual mean temperature measured in °C x 10 available originally at very high resolution (around 1 kilometer grid cells) from BIOCLIM (BIO12) and processed using ArcGIS.¹¹⁵ Alternative comparable data are also available for Brazil from IPEA based on the Climate Research Unit of University of East Anglia (CRU-UEA) project.

¹¹⁴<http://worldclim.com/>

¹¹⁵<http://www.worldclim.org/bioclim>

Rainfall: Annual precipitation in millimeters also available from BIOCLIM (BIO1) converted using ArcGIS. Alternative data are also available for Brazil from IPEA based on the CRU-UEA project.

Ruggedness: Terrain ruggedness index in millimeters, originally available from Nunn and Puga 2012) at high-resolution (30 x 30 arc-seconds) and later processed using ArcGIS.¹¹⁶

Slope: Similar to ruggedness, in thousandths of a percentage point, also originally from Nunn and Puga (2012) at the grid cell level and processed with ArcGIS.

Distance to River: Distance to the nearest river in decimal degrees is calculated using ArcGIS with the waterways shape file for South America.¹¹⁷

Distance to Coast: Distance to the nearest coast in decimal degrees is also calculated using ArcGIS using the world coastline shape file.¹¹⁸

Coastal Dummy: Alternatively, a simple dummy taking the value of 1 for a municipality that has direct access to the coast and 0 if landlocked, also calculated using ArcGIS.¹¹⁹

E. Historical Outcomes

Historical Literacy: Literacy and illiteracy rates are measured in percentages over the relevant population. Data for Argentina comes from the 1895 and 1914 censuses.¹²⁰ Data for Brazil is from the 1920 and 1940 censuses and data for Paraguay from the 1950 census.¹²¹ The municipal level data provides information for different age groups and for males and females separately. Data for Argentina (1895 and 1914) and Brazil (1920) further distinguish between native and foreign literacy rates, allowing for the exploration of heterogeneous effects.

Religion: The religion of the respondent is first recorded in the 1890 Brazilian Census. The Brazilian IBGE also reports the religion of the respondent for modern times.

Mixed Marriage: Data on the partner's race (white, mixed, caboclo and mestizo) are available from the 1890 Brazilian Census.

Language: Since Paraguay is a bilingual country, the 1950 Paraguayan census records the language of the respondent: Guarani, Spanish or both.

¹¹⁶<http://diegopuga.org/data/rugged/>

¹¹⁷Available, among others at: <http://mapcruzin.com/>

¹¹⁸See: <http://openstreetmapdata.com/data/coastlines>

¹¹⁹The standard agricultural suitability (FAO-GAEZ or University of Wisconsin SAGE) data is available at the 5-minute grid cell resolution, which is coarser than the municipality level data used in this paper.

¹²⁰The 1869 Argentina Census does not report literacy.

¹²¹The 1890 Brazil Census does not report literacy. I thank Vicky Fouka for sharing her Rio Grande do Sul historical literacy data.

F. Cultural and Experimental Variables

Altruism: From the household survey, in Guaranis, respondents were asked to imagine they received 1 million Guaranis and then asked how much of that amount they would donate to charity.

Positive Reciprocity: From a hypothetical trust game, in which an initial amount of 10,000 (about 2 dollars) is allocated to each individual. Any quantity transferred to the other person is multiplied by 3. Then the other person has to decide the allocation of the total amount: 10,000 plus the amount transferred multiplied times three. The answer for this exercise corresponds to the case in which the other person has transferred his / her full amount, for a total of 40,000 Guaranis to be redistributed. Answers were also recorded for 0 and 5,000 transfers for a total of 10,000 and 25,000 Guaranis to be redistributed.

Time Discounting: From the household survey, corresponds to the hypothetical answer (in Guaranis) to the payment expected to receive in 12 months in exchange for a payment of 1,000,000 Guaranis today.

Certainty Equivalence: From the household survey, corresponds to the hypothetical answer (in Guaranis) to the the certain payment the respondent would prefer to a 50-50 lottery of 0 or 1 million Guaranis. Can be used to construct measures of risk preferences (lover, neutral and averse).

Cheating Game: From the household survey, number of heads, when participants were prompted to toss a fair coin nine times and record the number of heads. In addition, they were informed that with 5 or more heads they will obtain an extra compensation for their participation (a box of tea, a traditional staple food with a one dollar value, aside from a notebook also of one dollar value).

Rotter Locus of Control: From the household survey, short version of Rotter (1954) psychological test going from low values (external control, minimum of 24) to high values (internal control, maximum of 48).

Handicrafts: The Brazilian Municipal Survey of 2006 records very detailed information on handicraft production, most importantly, embroidery.

Knowledge Transmission: The Paraguayan Cultural Module of 2011 contains very specific information about traditional knowledge of medicine and folktales, including inter-generational transmission and language of transmission.

Language: The main language of the respondent (Spanish, Guarani, both or other) was asked in Paraguay in the 2012 Household Survey.

Race: The percentage of indigenous population is reported by the IBGE for Brazil in 2010.

G. Individual Controls and Additional Data

Age: Individual control, from the household survey, in years.

Male: Individual control, from the household survey, 1 for males and 0 for females.

Race: Individual control, from the household survey, categorical variable for indigenous, mestizo, white, black and mulatto.

Marital Status: Individual control, from the household survey, categorical variable for single, married, in concubinage, divorced and widowed.

Siblings: Individual control, from the household survey, dummy variable 1 for yes 0 otherwise.

Children: Individual control, from the household survey, dummy variable 1 for yes 0 otherwise.

Immigrant Status: Individual control, from the household survey, dummy variable 1 for born in Paraguay 0 otherwise.

Population Density: Population counts are taken from the 2001 census for Argentina, the 2000 Brazilian census and the 2002 Paraguayan census, and area is as reported previously.

Pre-colonial Population Density: Number of indigenous people per square kilometer, taken from and described in detail in Maloney and Valencia Caicedo (2012).

Migration: Data on migration and resident status are reported for Brazil by the IBGE in 2010.

Hours Worked: Total number of hours worked for people 10 and older is taken from the 2010 Brazilian Census and the 2012 Paraguayan Household Survey.

Labor Force Participation: Labor force participation is available for Brazil through IPEA for 2000.

Occupation: From the Paraguayan Household Survey of 2012, I collect information on occupations including agriculture, manufacturing, commerce and services.

Inequality: A Theil index on income is available for Brazil from IPEA for 2000 and for Paraguay from the World Bank (2008).

Health: A series of health variables including mortality under 5, infant mortality, number of doctors, and Health Development Indexes are available for Brazil from IPEA for 2000.

Tourism: Data on the prevalence of touristic activities come from the Brazilian Municipal Survey of 2006.

II. Additional Results: Alternative Estimation Estrategies

I present in this section complementary empirical results. They include a alternative specifications for income, an intensity of treatment robustness specification and a new instrument.

B. Alternative Specifications

As a first pass of the income data I look at the impact of missions on income in Brazil using dummy variables. In this first specification, a municipality receives a value of 1 if it had a Jesuit mission in the past and 0 otherwise. This coarse measure assumes that the boundaries of the missions were strict and is mostly used for descriptive purposes.¹²² The missionary effect on logarithm of income appears positive, large and statistically significant at different distance thresholds (Figure A.5). This is true both for the full sample at around .8 log points as well as for progressively smaller samples (starting with 500 kilometers to the nearest mission in 100 decreases). The coefficients appear stable in magnitude and relatively larger at the local level. Because missionary presence might just be capturing different geographic and weather characteristics, I control for these variables directly in Figure A.6. Although now smaller in magnitude, at around .6 log points, the results are largely unchanged. The coefficients are again positive and significant, stable and larger at the local level. The results suggest that geographic conditions have a positive and significant effect, but that there is still an important role for the missionary treatment.

To formally assess the role of observable variables and unobservable characteristics, I calculate Altonji ratios (Altonji et al. 2005; Bellows and Miguel, 2009).¹²³ The intuition of this exercise is to see how large the selection in unobservables would need to be relative to observables in order for it to drive the results observed. For the full sample the ratio is 4.15 (Altonji et al. 2005 report 3.55) meaning that selection in unobservables would need to be that much higher to drive the results.¹²⁴ Technically, for this result to hold the R-squared of the regressions should be approaching the maximum R-squared (Oster, 2013). In this case the R-squared increases from around .3 to (a very

¹²²The missionary area covers around one million of the total ten million inhabitants in the sample.

¹²³For a similar application in a historical context, see Nunn and Wantchekon (2011).

¹²⁴I compare here the first estimates from Figures 4 and 5.

high) .66 in the localized sample. Although the results from this exercise are reassuring, I employ other strategies to deal with endogeneity in the paper.

I explore here other non-linear formulations, beyond the dummy variable and distance to the nearest mission specifications.¹²⁵ The first is a log-log rather than a log-linear specification. As can be seen in the first two Columns of Table A.2, this variation leaves the results largely unchanged. The coefficients are negative, significant and stable. If anything, they appear larger in the reduced sample. An alternative formulation uses concentric distance rings as opposed to continuous distance. This measure is a combination of the dummy and the distance formulation used previously. Namely, I use a dummy to ascertain whether the municipalities lie within 100 kilometers from a mission, in concentric increments of 100 kilometers up until 500 kilometers.¹²⁶ The results of this formulation, in Table A.2, again lead to the familiar pattern. Places closer to missions are richer today. This holds both in the full (Columns 3 and 4) and reduced (Column 5) samples. Lastly, I estimate a quantile regression, which shows that the missionary effect works not only at the mean but also at the median level of the sample (Columns 6 and 7).¹²⁷ Again, the results are larger at the local level. Taken together, the results using alternative formulations show the robustness of the Jesuit results for income.

B. Robustness: Intensity of Treatment

As has been discussed throughout the paper, the results presented are robust to alternative definitions, variables and formulations. In this section I focus instead on the intensity of missionary treatment. To do so, I estimate alternative econometric specifications with interaction effects.¹²⁸ In particular, I exploit historical information on the year of foundation, indigenous population and a dummy variable for whether the mission moved or not. Instead of only using distance to the

¹²⁵I also experiment with Conley standard errors, that take into account spatial auto-correlation, which leaves the results (not shown) unchanged.

¹²⁶From 500 to 600 is the excluded category.

¹²⁷This formulation also allows for testing robustness for outliers. As is standard, I use bootstrapped standard errors in this formulation. Quantile results for education (not shown) reveal large treatment effects for median and below median literacy levels.

¹²⁸I thank Pedro dal Bó and Esteban Aucejo for suggesting these formulations.

nearest mission as in Equation 2, I interact this variable with the year of foundation and or the mean of the indigenous missionary population. For all formulations I use information on the nearest mission as well as geographic and weather results. The results of this empirical exercise can be seen in Table A.3. In the Distance X Year of Foundation formulation in the first Column, the log coefficient is negative and significant, reflecting that not only distance to the nearest mission, but also how many years it was active, was important. The results are positive and significant when I use instead the mean of indigenous population divided by distance, again in logs (Column 2). So not only the number of years, but also the quantity of people treated appears as important. Combining this information, I estimate a model with population interacted with years of missionary activity normalized by distance. Once again the log coefficient is positive and statistically significant (Column 3). I also interact distance to the nearest mission with distance to the nearest river, as a proxy for isolation or market access, finding a negative effect (Column 4). Lastly, I explore whether missions that moved during some point in their history have a differential effect.¹²⁹ I find using a dummy variable that indeed such movers had less of an impact (significant at the 10%) in the long-run (Column 5). Taken together, the results in this section show that the intensity of the Jesuit treatment also mattered in terms of years of exposure and population size.

C. Distance to Tordesillas

As an alternative instrument, I use an earlier even border change than the 1750 Treaty of Madrid. On the June 7, 1494, two years after the Discovery of the Americas, the Spaniards and the Portuguese signed the treaty of Tordesillas to delimit their empires in the New World. The Tordesillas line followed the meridian 370 leagues from the Cape Verde islands (46°30' W of Greenwich), determining that any new territory east of the line would be Spanish and anything West of it would be Portuguese (Figure A.7). Of course this left Spain with all the newly-found Caribbean islands. The demarcation of the line preceded the discovery of South America during the third voyage of Christopher Columbus in 1498. As a result, a significant territory of South America was left under Portuguese jurisdiction and colonized accordingly.

¹²⁹Approximately half of the missions moved at some point in their history.

The Tordesillas line also had important implications for the Jesuit Missions. As was discussed in the placebo section, proximity to the Portuguese territories represented a generalized threat from the slave hunting *bandeirantes*. In the Spanish Empire the New Laws issued by Charles V in 1542 aimed to protect the indigenous inhabitants from colonial exploitation. The laws (and their enforcement) on the Portuguese side were more lenient in this regard.¹³⁰ As a result, the *bandeirantes* would often raid the Spanish territories, capture indigenous slaves and return to their Portuguese bases.¹³¹ This meant that missions that were located farther away from the line had a higher probability of survival.

I take here as instrument for the location of the Jesuit Missions the (horizontal) distance from the Tordesillas line. In particular, I hypothesize that the probability of survival of a mission is inversely proportional to the distance from the Tordesillas line. This is all conditional on being to the left of the line, as can be seen in Figure A.7, so I abstract from the actual consequences of being on a particular side of it. I include country fixed effects, and control for geographic and weather characteristics. The assumption is that distance to Tordesillas influenced the location of the missions, but does not affect the outcomes of interest directly. As was seen in the placebo section, I find no direct effect of the attacks in the long run.¹³² The results can be seen in Table 9. Again the first stage is very strong. The instrumented coefficient for missionary distance emerges positive and significant for illiteracy (Column 3) and negative and significant for income (Column 7), as in the previous estimates.

To further explore the robustness of the instrumental variable results, I combine all instruments in Columns 4 and 8 of Table 9. I restrict the sample to the Brazilian municipalities, to be able to use the distance to Asuncion instrument. The sign and significance is preserved both for the education and income results. I cannot reject Hausman tests for income and education with the three instruments.¹³³ Results are robust to estimation with both 2SLS and LIML.

¹³⁰In the Spanish Americas, the New Laws were complemented by the Alfaro Ordnances of 1612 (Ganson, 2003).

¹³¹As can be seen dramatically in Roland Joffé's *The Mission*.

¹³²I control again for the direct distance to São Paulo, leaving the results essentially unchanged.

¹³³Of course, this hinges on the assumption of the estimates with one instrument, in this case distance to Asuncion, being consistent.

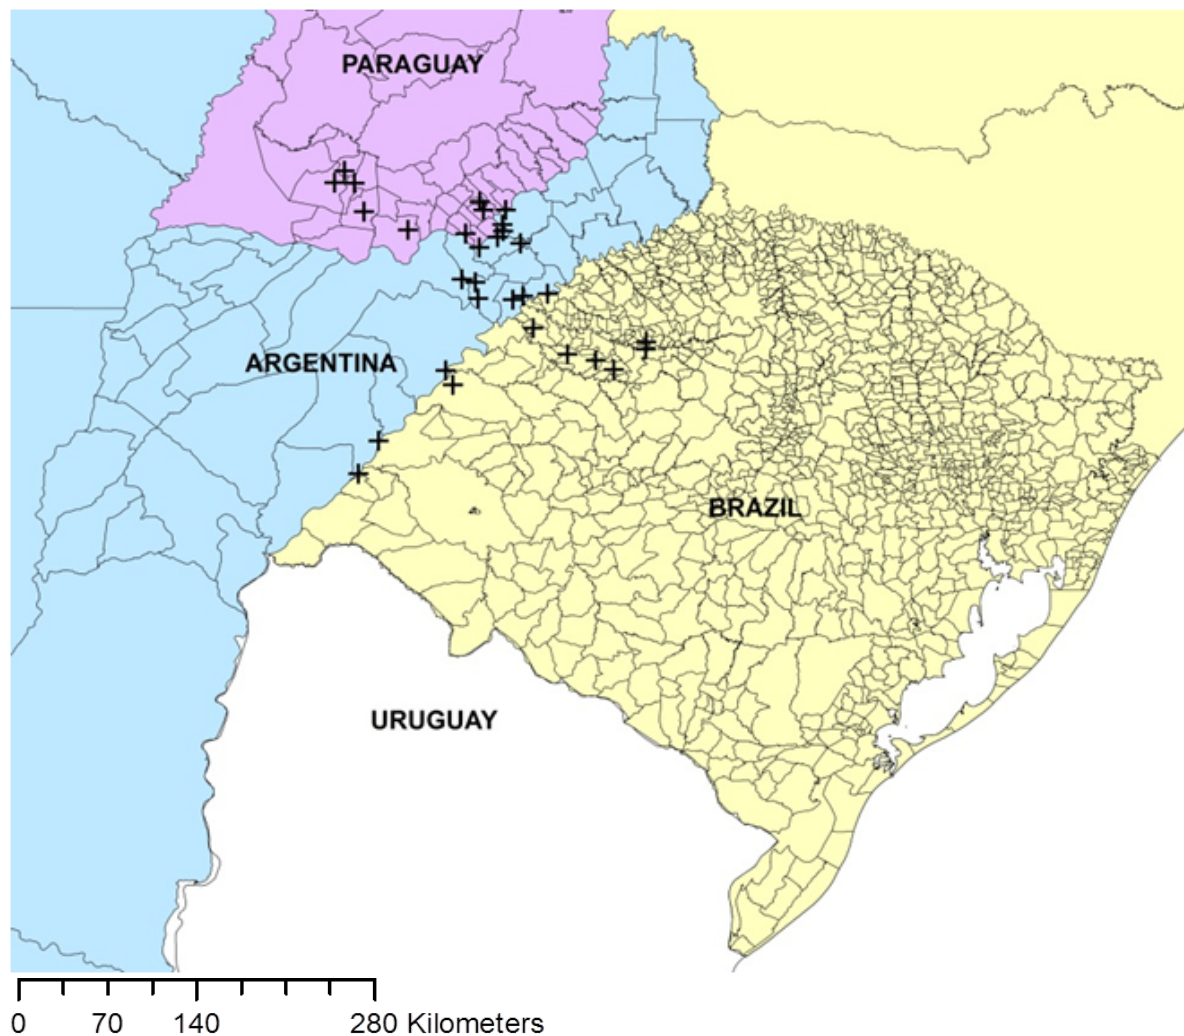

Figures

Figure 1. Location of the Guarani Jesuit Missions in Latin America

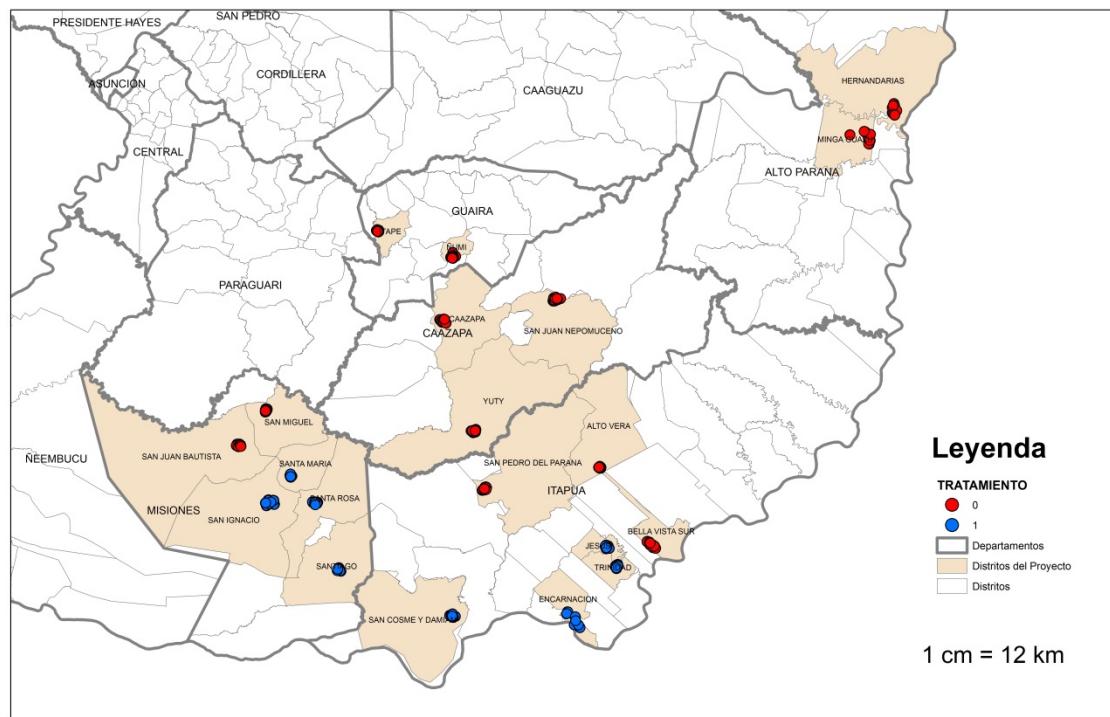

Note: The map shows the location of the Guarani Jesuit Missions, along with state level boundaries for Argentina, Brazil and Paraguay, and national level boundaries for the rest of Latin American countries.

Figure 2. Location of the Guarani Jesuit Missions in Argentina, Brazil and Paraguay

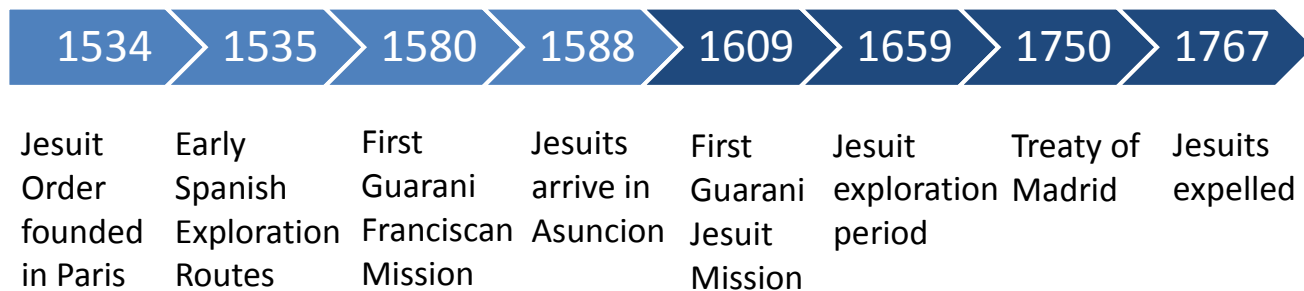

Note: The map shows the exact location of the Guarani Jesuit Missions, along with municipal level boundaries for the states of Corrientes and Misiones (Argentina), Itapua and Misiones (Paraguay) and Rio Grande do Sul (Brazil), and state boundaries for other states in Argentina, Brazil and Paraguay.

Figure 3. Household Survey Map: Southern Paraguay

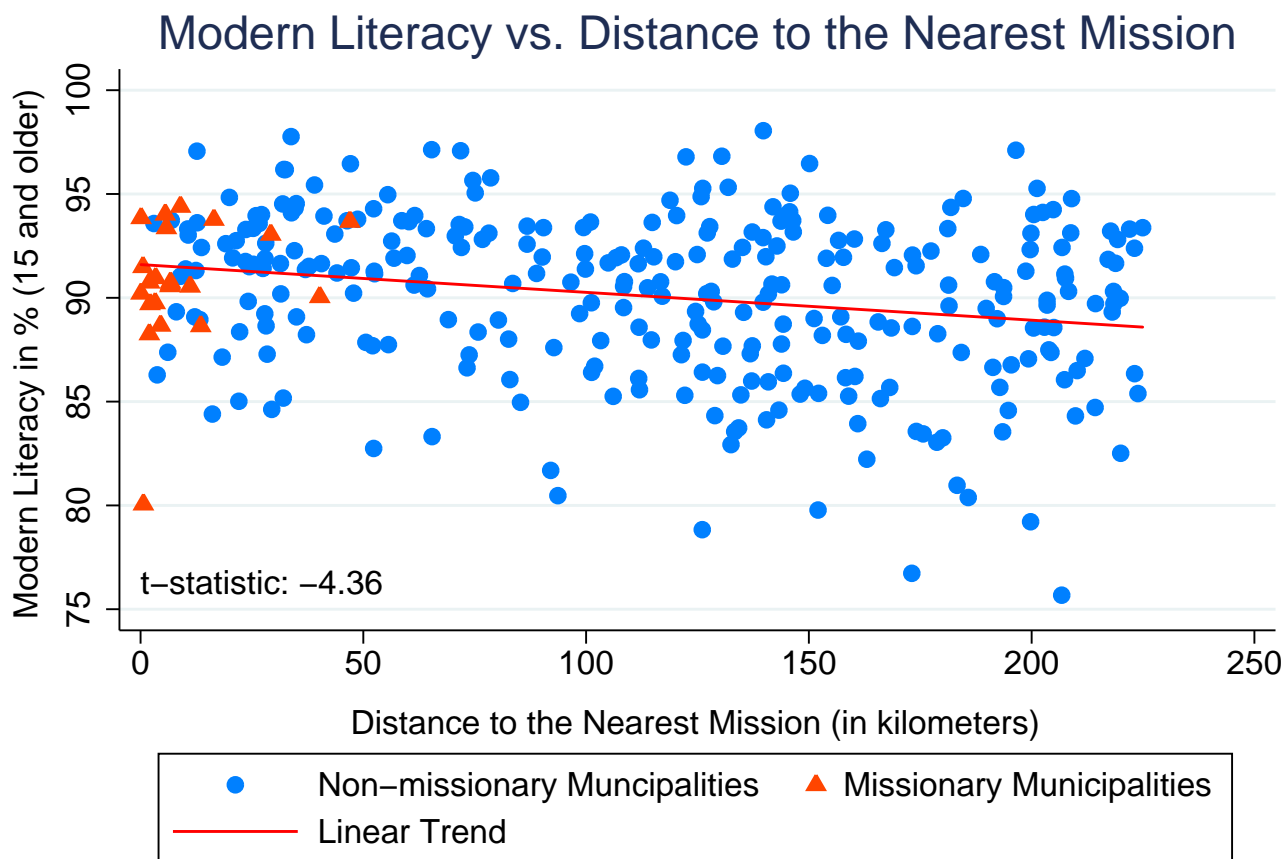

Note: The map depicts the survey areas with non-missionary districts (in red) and missionary districts (in blue) along with district boundaries for Southern Paraguay.

Figure 4. Historical Timeline

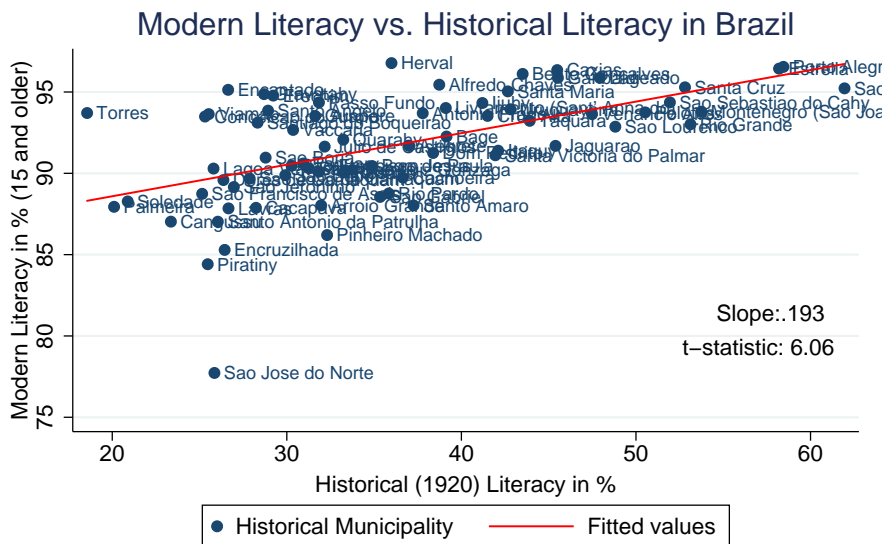

Note: The figure depicts the key historical events studied in the paper, the darker shade of blue depicts the 150 years of Jesuit missionary intervention.

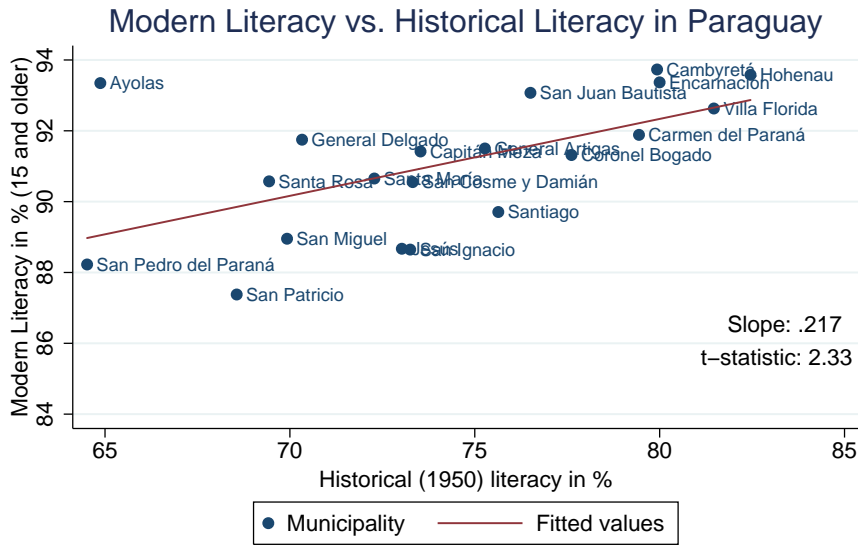

Figure 5. Literacy vs. Missionary Distance: Unconditional Plot

Note: Unconditional plot of 2000 literacy in percentages for people aged 15 and older in Argentina, Brazil and Paraguay versus distance of the municipality centroid in kilometers to the nearest Jesuit mission. Orange triangles represent missionary municipalities and blue dots non-missionary ones. The red line is a linear trend. The sample is restricted to a 225 kilometers distance threshold.

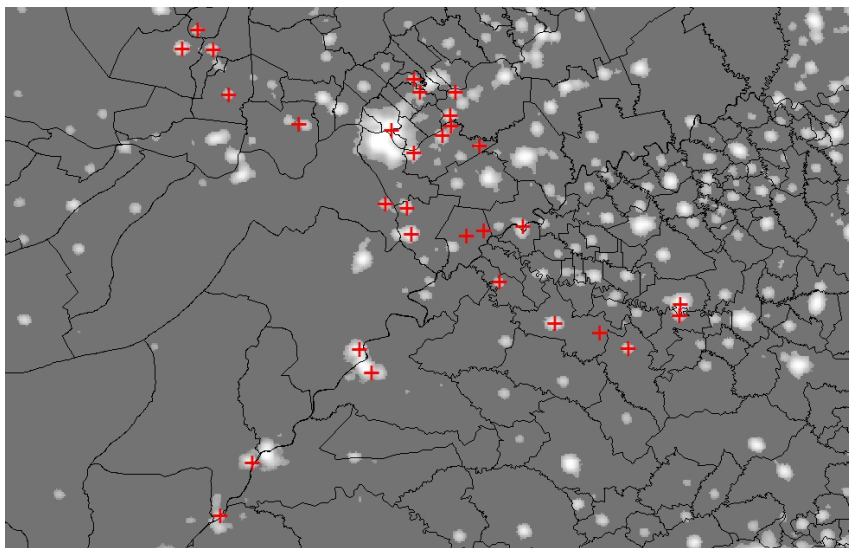

Figure 6. Modern vs. Historical Literacy in Argentina, Brazil and Paraguay: Unconditional Plots

Note: Unconditional plots of 2000 literacy in percentages for people aged 15 years and older in Argentina and Brazil on 1895 literacy in percentages in Argentina, 1920 in Brazil, and 1950 in Paraguay. Blue dots represent municipalities with historical names and red lines are linear trends.

Figure 7. Nighttime Satellite Maps of the Guarani Jesuit Missionary Area

Note: The maps depict the nighttime satellite images (F18-2010) of the Guarani Jesuit missionary area along with municipal level boundaries for the states of Corrientes and Misiones (Argentina), Itapua and Misiones (Paraguay) and Rio Grande do Sul (Brazil), without and with the location of the Guarani Jesuit Missions (red crosses).

Figure 8. Missionary Effect on Rotter Locus of Control Scale

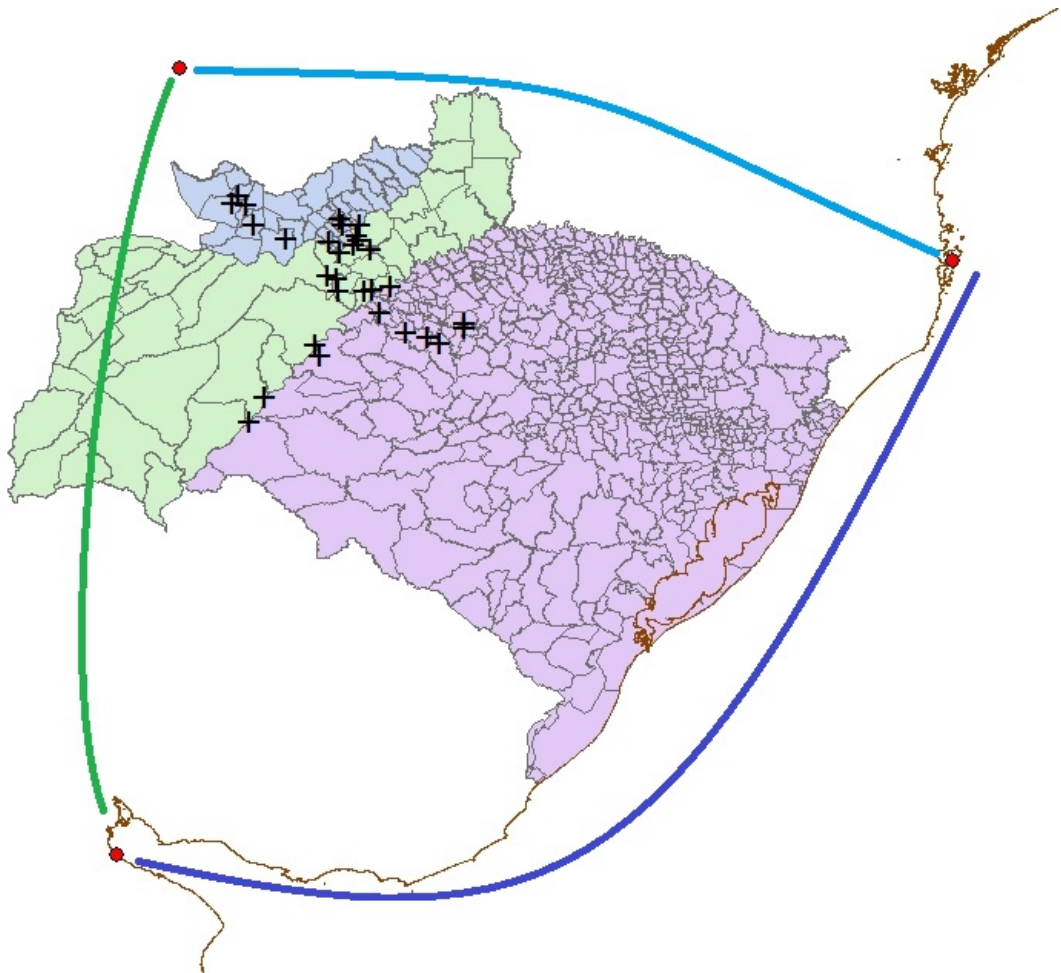

Note: The figure depicts a density plot of the Rotter Locus of Control Scale (going from low values of external control to high values of internal control), separating between non-missionary areas (in circles) and missionary areas (in triangles)

Figure 9. Historical Population of Jesuit and Franciscan Guarani Missions (1640-1760)

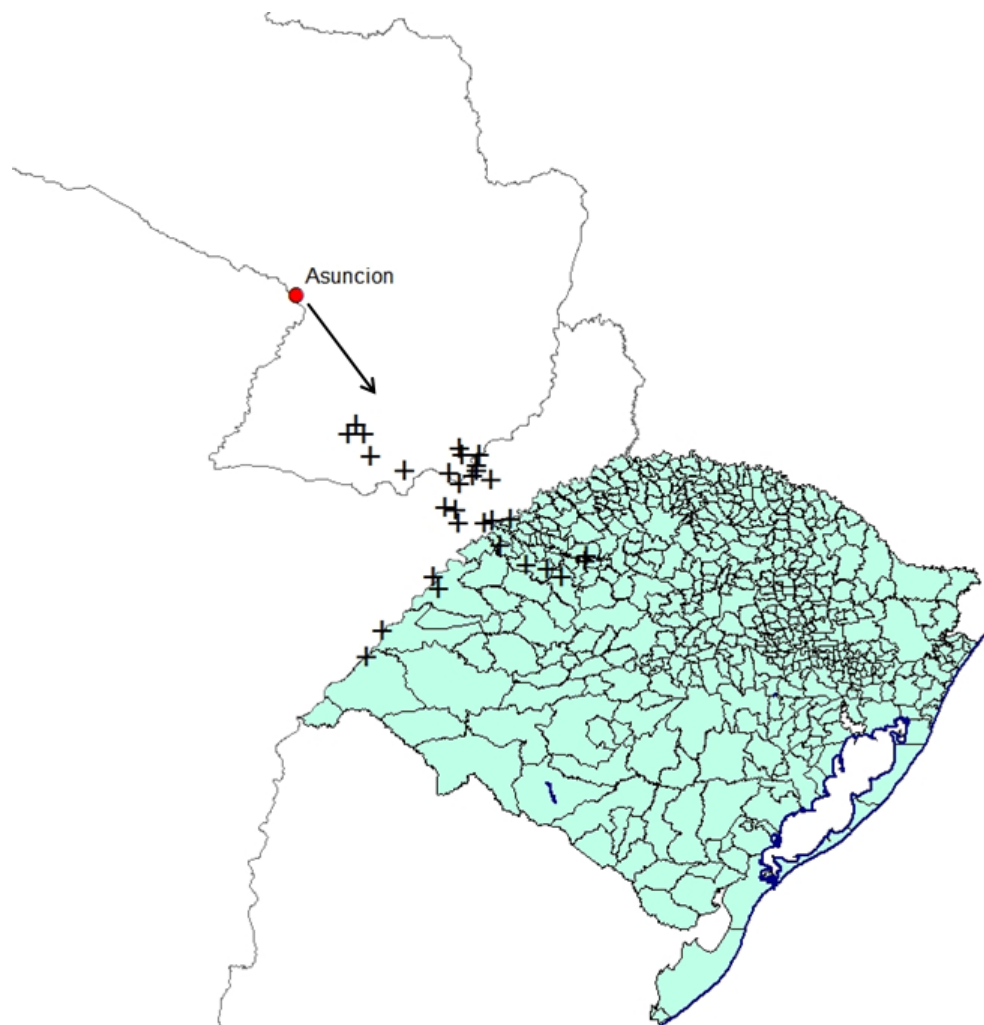

Note: This graph plots average mission population for Jesuit (blue diamonds) and Franciscan (red dots) Missions from 1640 to 1760.

Figure 10. Map of the Guarani Jesuit Area along with Exploration Routes

Note: The map shows the location of the Guarani Jesuit missions along with municipal level boundaries for the states of Misiones and Corrientes (Argentina), Misiones and Itapua (Paraguay) and Rio Grande do Sul (Brazil). The lines mark the expeditions by Pedro de Mendoza, Alvar Nuñez Cabeza de Vaca, Juan de Ayolas and Domingo de Irala. The red points demarcate Asuncion, Buenos Aires and Santa Caterina.

Figure 11. Map of Rio Grande do Sul with the Direction of the Jesuit Missions from Asuncion

Note: The map shows the location of Asuncion, the Guarani Jesuit Missions, along with municipal level boundaries for the state of Rio Grande do Sul (Brazil), and national level boundaries for Argentina and Paraguay.

Figure 12. Hours Worked vs. Missionary Distance: Brazil

Note: Unconditional plot of percentage of people reporting working 15 to 39 hours in Brazil in 2010 versus distance to the nearest Jesuit mission in kilometers. Municipalities in green circles, blue linear fit with gray 95% confidence bands.

Note: The table shows the coefficient of distance to the nearest Jesuit mission in kilometers (Equation 2). The dependent variable is the logarithm of income per capita in 2000 in Brazil in columns 1 to 3, Unsatisfied Basic Needs (UBN) Poverty Index in Argentina and Paraguay at the individual level in Columns 4 and 5, and the household level in Columns 6 and 7. Geographic controls include distance to the nearest coast, distance to the nearest river, altitude, temperature, area, rainfall, latitude and longitude. Please refer to the paper for units and additional details of these variables. Estimation is by OLS with state fixed effects in Columns 4 to 7. The results are for the full, <400, <200 and <100 kilometers from the nearest Jesuit mission samples. Robust standard errors in parentheses *** p<.01, ** p<.05, *p<.1

Appendix Figures

Figure A.1. Historical Population of the Guarani Jesuit Missions (1650-1780)

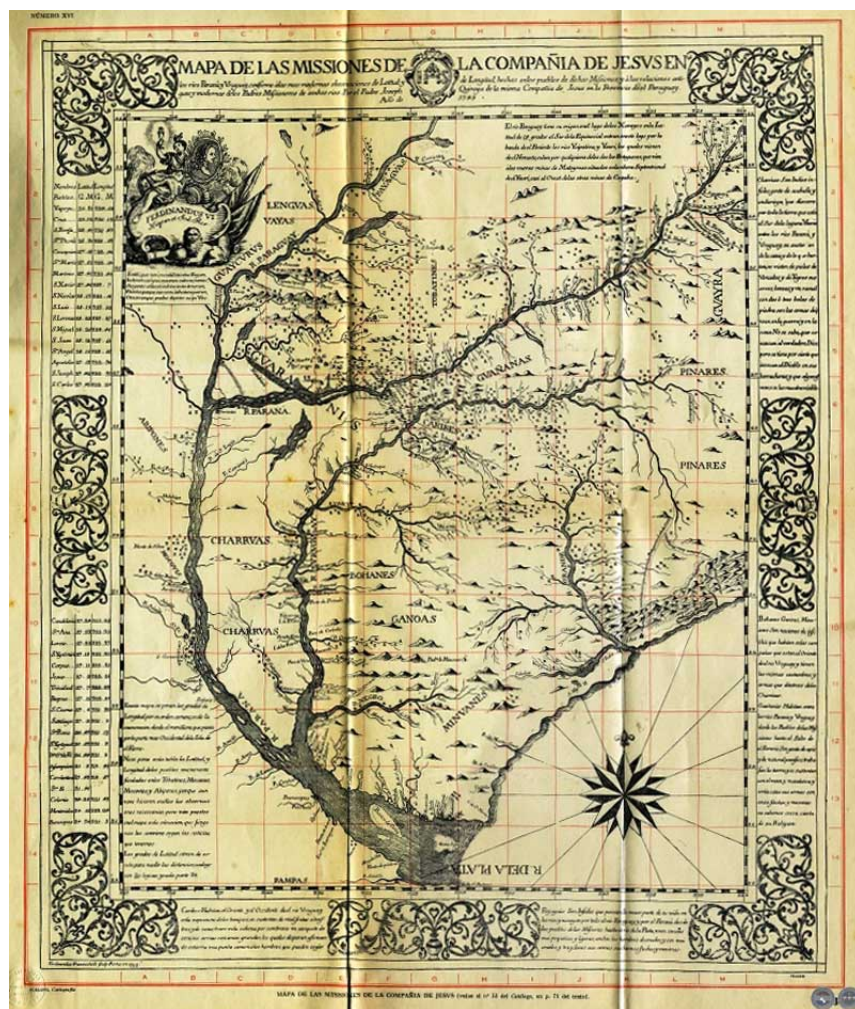

Note: Total contemporary Guarani Jesuits Missions population counts from surviving records. The red line represents 1767, which corresponds to the expulsion of the Jesuits from Latin America.

Figure A.2. Historical Blueprint of a Guarani Jesuit Mission

Note: Urban blueprint of the Jesuit Mission of San Ignacio de Miní taken in 1899 by Juan Queirel, taken from Hernández (1913).

Figure A.3. Historical Map of the Jesuit Missions of Paraguay

Source: Drawn by Gustavo Laterza (1647).

Figure A.4. Nighttime Satellite Maps of the Guarani Jesuit Missionary Area

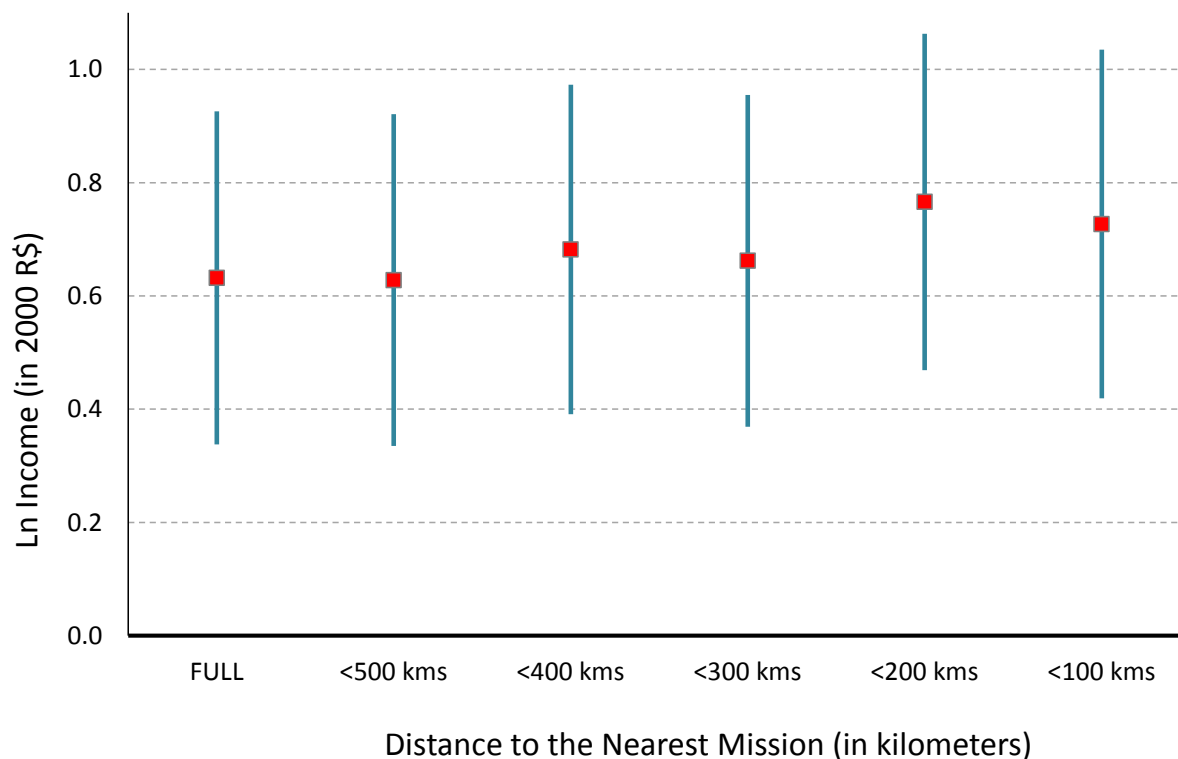

Note: The maps depict the nighttime satellite images (F18-2010) of the Guarani Jesuit missionary area along with municipal level boundaries for the states of Corrientes and Misiones (Argentina), Itapua and Misiones (Paraguay) and Rio Grande do Sul (Brazil), without and with the location of the Guarani Jesuit Missions (red crosses).

Figure A.5. Missionary Effect on Income (Dummy Formulation): Brazil

Note: This graph plots the unconditional coefficients for a regression of the logarithm of (2000) income in Brazilian Reals on a dummy for missionary presence at different distance thresholds. Point estimates are represented by red squares and 95% robust error bands by blue lines.

Figure A.6. Missionary Effect on Income (Dummy Formulation) with Geographic and Weather Controls: Brazil

Note: This graph plots the coefficients for a regression of the logarithm of (2000) income in Brazilian Reals on a dummy for missionary presence with geographic and weather controls (altitude, area, temperature and rain) at different distance thresholds. Point estimates are represented by red squares and 95% robust error bands by blue lines.

Figure A.7. Latin America Map with Tordesillas Line

Note: Map of Latin America with state level boundaries for Argentina, Brazil and Paraguay, and national level boundaries for the rest of Latin American countries along with the Tordesillas line, dividing the Spanish and Portuguese empires.

R-squared	0.51	0.51	0.55	0.388	0.873

Note: The table shows the coefficient of the logarithm of distance to the nearest Jesuit interacted with year of foundation, mean population and distance to the nearest river in Columns 1 to 4. Mission moved is a 0/1 for whether or not the nearest Jesuit mission moved. The dependent variable is the logarithm of income in 2000 for Brazil and Paraguay. Geographic controls include distance to the nearest coast, distance to the nearest river, altitude, temperature, area, rainfall, latitude and longitude. Please refer to the paper for units and additional details of these variables. Estimation is by OLS. Robust standard errors in parentheses *** p<.01, ** p<.05, *p<.1
